This report addresses some corrections to the original July 2, 2014 Technical Report. There were two typographical errors where the word “tons” were used instead of “tonnes.” Also, there was a mathematical addition error in Table 21.1 on page 132 where the initial capital was added twice in the total capital estimate. This error has been corrected.

These errors were corrected July 10, 2014

AUTHOR'S CERTIFICATE – SCOTT E. WILSON CPG

I, Scott E. Wilson, of Highlands Ranch, Colorado, do hereby certify:

1. I am currently employed as President by Metal Mining Consultants Inc., 9137 S. Ridgeline Blvd., Suite 140, Highlands Ranch, Colorado 80129.
2. I graduated with a Bachelor of Arts degree in Geology from the California State University, Sacramento in 1989.
3. I am a Certified Professional Geologist and member of the American Institute of Professional Geologists (CPG #10965) and a Registered Member (#4025107) of the Society for Mining, Metallurgy and Exploration, Inc.
4. I have been employed as either a geologist or an engineer continuously for a total of 25 years. My experience included resource estimation, mine planning, geological modeling and geostatistical evaluations, mine planning, project development, and authorship of numerous technical reports and Preliminary Economic Assessments of various projects throughout North and South America.
5. I have read the definition of "Qualified Person" set out in National Instrument 43-101 ("NI 43-101) and certify that by reason of my education, affiliation with a professional association (as defined in NI 43-101) and past relevant work experience, I fulfill the requirements to be a "Qualified Person" for the purposes of NI 43-101.
6. I made a personal inspection of the Lincoln Hill Property on February 4, 2014 for 1 day.
7. I am responsible for the preparation of the technical report titled Preliminary Economic Assessment –Rye Patch Gold Corp., Lincoln Hill Property, Pershing County, Nevada, USA, dated July 2, 2014 Technical Report.
8. I have had prior involvement with the property as the author of a technical report titled Technical Report – Rye Patch Gold Corp., Lincoln Hill Property, Pershing County, Nevada, USA dated September 17, 2012.
9. As of the effective date of this report of May 21, 2014, to the best of my knowledge, information and belief, the portion of the Technical Report for which I am responsible contains all scientific and technical information that is required to be disclosed to make the portion of the Technical Report for which I am responsible not misleading.
10. That I have read NI 43-101 and Form 43-101F1, and that this Technical Report was prepared in compliance with NI 43-101.
11. I am independent of the issuer applying all of the tests in Section 1.5 of NI 43-101.
12. I consent to the filing of the Technical Report with any stock exchange and other regulatory authority and any publication by them, including electronic publication in the public company files on their websites accessible by the public, of the Technical Report.

Dated: July 2, 2014

Scott E. Wilson, C.P.G.

AUTHOR'S CERTIFICATE – BILL PENNSTROM JR.

I, William Pennstrom, Jr., President of Pennstrom Consulting Inc., do hereby certify that:

1. I am a consulting metallurgical engineer and President of Pennstrom Consulting, Inc. 2728 Southshire Rd. Highlands Ranch, CO 80126, USA.
2. I am a graduate of the University of Missouri Rolla (currently known as Missouri S&T) with a BS degree in Metallurgical Engineering. I am also a graduate of Webster University in St. Louis, MO, with a MA degree in Business Management.
3. I am a Registered Member in good standing of the Society of Mining, Metallurgy and Exploration. I am also a Qualified Professional Member of the Mining and Metallurgical Society of America.
4. I have worked in the Mineral Processing Industry for a total of 28 years since before, during, and after my attending the University of Missouri. I have been an independent process/metallurgical consultant for the last nine (9) years for the mining industry.
5. I have read the definition of "qualified person" set out in National Instrument 43-101 and certify that by reason of education, experience, independence and affiliation with a professional association, I meet the requirements of an Independent Qualified Person as defined in National Instrument 43-101.
6. I am responsible for the preparation of Sections 13 and 17, and relevant portions of Sections 1, 2, 18, 21 and 26 of the technical report titled "Preliminary Economic Assessment –Rye Patch Gold Corp., Lincoln Hill Property, Pershing County, Nevada, USA, dated July 2, 2014 (the "Technical Report"). I visited the Lincoln Hill Project on February 4, 2014 for one day.
7. Prior to being retained by Rye Patch Gold Corp., I have not previously worked on this deposit.
8. As of the effective date of this report of May 21, 2014, to the best of my knowledge, information and belief, the portion of the Technical Report for which I am responsible contains all scientific and technical information that is required to be disclosed to make the portion of the Technical Report for which I am responsible not misleading.
9. I am independent of the issuer applying all of the tests in section 1.5 of National Instrument 43-101.
10. I have read National Instrument 43-101 and Form 43-101F1, and the Technical Report has been prepared in compliance with that instrument and form.

Dated July 2, 2014

1 SUMMARY

1.1 INTRODUCTION

At the request of Rye Patch Gold Corp. ("Rye Patch"), this Preliminary Economic Assessment (PEA) has been prepared by Metal Mining Consultants Inc. (MMC) on the Lincoln Hill property (Lincoln Hill), Pershing County, Nevada. The purpose of this report is to provide Rye Patch and its investors with an independent scoping study on the potential to economically extract mineral resources at Lincoln Hill. This PEA was based on a resource and property evaluation completed by Scott E. Wilson Consulting, Inc. (now MMC) and reported in the technical report on the Property dated September 27, 2012, which is publically available at www.sedar.com. This report conforms to the standards specified in Canadian Securities Administrators' National Instrument 43-101, Companion Policy 43-101CP and Form 43-101F.

Rye Patch Gold US Inc. ("Rye Patch US"), a wholly-owned subsidiary of Rye Patch, acquired Lincoln Hill in 2007 based on the geological setting and its strategic location near their recent gold discoveries at the Wilco Project, located approximately 6 km to the west. Lincoln Hill is located in western Nevada, approximately 185 km (115 mi) east of Reno, Nevada. It is readily accessible from Interstate 80 (I-80) east of Lovelock, Nevada. Lincoln Hill consists of 142 unpatented lode mining claims (2 "Kings Ransom" claims, 4 "King Tut" claims, 6 "LHL" claims, 16 "ALH" claims, 6 "WMC" claims, 1 "Rochester Bonanza" claim, 2 "Raven" claims, 41 "LY" claims, 16 "LYF" claims, 24 "GG" , and 24 "LH" claims,) and 2 patented lode mining claims, Abe Lincoln #2 and Blue Bird. The claims are located in all or portions of sections 12 and 13, T28N, R33E, and sections 6, 7, 18 and 19 T28N, R34E, MDBM.

Rye Patch US has entered to three exploration agreements and staked claims at Lincoln Hill. The area covered by the agreements includes a total of 37 unpatented and 1 patented lode mining claims which cover approximately 536.23 hectares (1325 acres) and three leased parcels which cover 208.41 hectares (515 acres) for a total of 744.64 hectares (1,840 acres).

Effective November 7, 2007, Rye Patch US signed the Lincoln Hill Area Lease with an Option to Purchase Letter of Intent Agreement with Mountain Gold Exploration, Inc. (MGE) and Lane Griffin (LG) (the MGE/LG Agreement). This agreement covers 34 unpatented and 1 patented lode mining claims. Annual payments of cash and Rye Patch stock are due each November 7. There is an underlying lease, the Fialdini-Mahar Lease and Work Commitment, and Rye Patch US has assumed the work commitments. These annual commitments are cumulative and have been satisfied through 2013. The next payment is due November 7, 2014.

Effective September 8, 2009, Rye Patch US entered into an Agreement for the Sale and Purchase of Unpatented Mining Claims (Walker Agreement) and a Warranty Deed with Reserved Royalty with Robert Walker (Walker). These documents include 3 unpatented lode mining claims and reserve a 4% NSR to Walker, which can be bought down for $100,000 for each percentage. Annual cash payments are due each September 8 and the final payment was made September 8, 2013, and Rye Patch US owns the Raven, Raven #1 and Rochester Bonanza unpatented claims subject to a 4% NSR due to Walker.

Effective October 2011, Rye Patch US entered into a lease agreement with Nevada Land and Resource Company, LLC for three parcels of land totaling approximately 2.1 square kilometers (515 acres) located adjacent to the Lincoln Hill project. Rye Patch pays US $18.46 per acre for the first five years of the lease and $19.43 per acre starting in year six to keep the lease in affect. Annual cash payments are due each October.

Rye Patch US staked and owns the remaining 105 unpatented claims. The second patented claim, Blue Bird, was granted, transferred, and conveyed to Rye Patch US as part of the settlement in a legal dispute with Coeur Rochester mines in June 2013.

In October 2011, a group of LH unpatented lode claims were located immediately south and adjacent to the Lincoln Hill project. These LH claims became part of a legal dispute between Rye Patch Gold US Inc. and Coeur Rochester Mining. The legal dispute was resolve in June of 2013, and Rye Patch Gold US Inc. retained title and interest to certain LH claims totaling twenty-four unpatented lode claims named LH 136 to LH 156, LH 209, LH 211, and LH 501. In addition, Coeur Rochester granted, conveyed, and transferred title and interest of the Blue Bird patent, Patent No. 604728, Mineral Survey No. 4252, located in the SW1/4 of Section 18, T.28N., R.34E, to Rye Patch Gold US Inc.

The Lincoln Hill property is located in the Rochester mining district, in the southwest flank of the Humboldt Range. The Spring Valley mining district is to the east and north and the Sacramento district is to the west. The Rochester district has produced more silver than any other district in Pershing County. During the 1860s there was prospecting across the entire Humboldt Range. The Rochester mining district deposits were worked extensively from 1912-1929 at which time the Lincoln Hill area was producing gold. There are no specific production figures for Lincoln Hill, although gold and silver have been mined from the hill through the 1980s. The Lincoln Hill gold and silver production is included in the Rochester district figures.

Since 1980 two companies have explored Lincoln Hill. During the 1980s, Coeur Exploration conducted surface exploration activities and drilled 8 RC holes into the upper eastern portion of the altered and mineralized zone. During 2001 and 2002, Newmont exploration completed geological mapping, surface and underground rock sampling and then drilled 8 RC holes. Newmont's drilling was primarily outside the main area of surface alteration and mineralization and they were likely searching for lateral and vertical extensions of the mineralizing system.

1.2 GEOLOGY AND MINERALIZATION

Lincoln Hill lies in the west-central portion of the Great Basin part of the Basin and Range Physiographic Province. The Great Basin is characterized by north to northeast trending ranges separated by wide flat valleys. In this part of Nevada, the ranges are generally made up of Mesozoic and Tertiary volcanic and sedimentary rocks. The Mesozoic sedimentary rocks have been classified into five major depositional groups of strata (Johnson, 1977). The groups that are exposed in the Humboldt Range are the Koipato and Star Peak Groups. The Koipato is comprised of nonmarine volcanic and sedimentary rocks. Deposition of the Koipato was accompanied by faulting and tilting which caused its present distribution

to be discontinuous across this portion of Pershing County. The geology of this part of the Humboldt Range has been studied extensively because it has the most complete section of the Koipato Group and it has a long history of silver and gold production, primarily from the Rochester Mine.

The Rochester Rhyolite hosts precious metal mineralization at Lincoln Hill and is divided into three sub units. The Basal Unit includes crystal tuffs, lapilli lithic tuffs and breccias. In outcrop it consists of intensely silicified, locally argillized, fine grained tuff. In core, the unit shows a more complex assemblage of volcanic rocks. Mineralized breccias occur mainly along high angle faults and consist of 1-6 cm diameter fragments of felsic volcanic rocks and some quartz in a fine grained matrix with abundant limonite and hematite. The Intermediate Unit is comprised of felsic tuffs that can exhibit well developed foliation that can be cataclastic and mylonitic. The Upper Unit is host to the ornamental dumortierite-rich rock. Andalusite, tourmaline and massive sericite occur in a strongly pervasively silicified felsic rock with veins and stockwork.

Lamprophyre dikes cut the Rochester rhyolite. They are argillized in places and can have a strong stockwork along the contact with the host Rochester Rhyolite. Au+Ag can occur along this Lamprophyre-Rochester contact. The Rochester Rhyolite is overlain by a massive dark gray limestone in the southwestern portion of the property. The limestone is locally cut by quartz veins or quartz stockwork.

Structurally, the district lies within a broad asymmetrical antiform that is cut by later north-trending faults. In the core of the Lincoln Hill mineralized area, the rock units are oriented E-W, dipping gently to south. NNW-SSE striking structures are also common at Lincoln Hill.

Lincoln Hill lies within the newly named Oreana Trend (Pinto da Silva and Howald, 2009). This mineralized corridor extends from the Willard/Colado (Wilco) area to the Spring Valley deposit. It is characterized by the alignment of recent and historic gold and silver deposits and occurrences.

At Lincoln Hill, the Rochester Rhyolite is intensely altered over an extensive area with minimum dimensions of 5,000’ long by 1,000’ wide by 1,000’ vertical. Silicification and argillization are the most conspicuous alteration and they envelop most of the mineralization. A high-grade, coarse-gold-bearing quartz-tourmaline-sericite-clay altered stockwork-vein system is associated with N30º to 60ºW striking, altered lamprophyre dikes. An additional later high-grade, coarse-gold, hematitic-clay altered tectonic fault-fracture system, which strikes N45°E, intersects and slightly offsets the lamprophyre dikes and associated gold-silver mineralization. Low-grade gold and silver mineralization is associated with quartz veinlets oriented northwest to southeast, and a close association with pervasive silicification. This blanket-like mineralized zone starts at the surface and has been drilled to a depth of 500 feet.

Lincoln Hill is a high-grade, gold-silver-quartz-pyrite-tourmaline-sericite stockwork vein system overprinting a large low to moderate grade disseminated replacement precious metal mineralizing system. The host rocks are the Permo-Triassic island arc volcanic rocks of the Koipato Group. Gold mineralization has been identified over an area 1.6 by 2.4 km (1.5 by 1 mi) and to a depth of >305 m (1000 ft). Rye Patch US believes that the folding faulting, alteration and mineralization are related to

several porphyry-style intrusions emplaced in this portion of Nevada. There are likely multiple mineralizing events which have deposited and remobilized the precious metals. The separation of these events at Lincoln Hill is critical in defining the areas prospective for concentration of gold and silver.

Gold occurs in several distinct "areas" at Lincoln Hill (Main, Shaft, Lamprophyre, Flat and Raven zones). Some of the common characteristics are: 1) Dense replacement silicification and quartz stockwork veins, 2) Argillization outside the silicification, 3) Lack of pyrite, 4) Quartz limonite and hematite stockworks and 5) Higher grade gold at structural intersections.

The Main Zone is characterized by high-angle N50E veins with lesser northwest and east-west trending structures. The sub-horizontal silicification with low-grade gold and silver mineralization is exposed at the surface and has been drilled to a depth of 152 m (500 feet). The Shaft Zone is characterized by high-angle N60E veins. The Shaft Zone is open to the northeast and southwest. The Lamprophyre Zone follows the N40 W trending lamprophyre dike. Gold mineralization occurs in stockwork veins and veinlets on the selvages and later high-grade, coarse-gold is associated with a hematite-clay altered N45E trending tectonic fault-fracture system (manifested by breccias). These breccias intersect and slightly offset the lamprophyre dikes and associated gold-silver mineralization. The Flat Zone is between the Main/Shaft zone areas and an untested northeast trending zone. The Raven Zone is characterized by steeply dipping N50E structure and is open to the southeast.

1.3 DRILLING AND SAMPLING

Historically, since 1988, Rye Patch US and its predecessors have drilled 123 exploration holes totaling 19,579 meters of drilling. These drilling efforts resulted in the discovery of a high-grade structurally controlled gold and silver resource. The potential to add additional resources and expand mineralized zones at the Lincoln Hill project is excellent.

The current sample collection, assaying and certification of assays are consistent with current operating practices. The sampling methods are standardized and tracked by Rye Patch personnel. Sample preparation, analysis and security is handled by reputable laboratories. All data is verified before being entered in to the drillhole databases for grade estimation.

Rock chip samples were collected by Rye Patch US primarily to determine the areas with the highest grade gold mineralization. At each sample site the location, rock type, formation, degree and type of alteration, mineralization and sample type were recorded. This work followed industry standards and was adequate for the geology, mineralization and level of exploration conducted at Lincoln Hill.

Rye Patch US used industry standard practices during their drilling programs. Both RC and core were collected (98 RC holes and 9 core holes). Drill holes were oriented to cross the mineralized zones based on surface and underground geologic mapping and the results of historic drilling. The RC samples were collected for each 1.5 m (5 ft) interval over the full length of the drill holes. Dry samples were taken in the upper 6 m of the hole and split. Casing was set and water was injected through the remainder of the hole. Samples were split using a rotating wet splitter.

There were 9 core holes drilled by Rye Patch US at Lincoln Hill and all the drilling was HQ or NQ. Rye Patch US sampled on 5 foot intervals, adjusting the sample widths when geology or mineralization changes were noted. Forty three drill holes were surveyed for deviation and most did not deviate more than a few degrees. Rye Patch US utilized blanks, reference standards and duplicate samples to monitor quality control of their drill samples.

The sampling methods were standardized. Sample preparation, analysis and security was handled by reputable laboratories and all data was verified before entering into the drill hole database for use in the resource estimation.

1.4 MINERAL RESOURCES

MMC generated the mineralized resource calculation for the Lincoln Hill Project using industry accepted standards. Mineralization has been categorized as either 1) Oxide mineralization or 2) Sulphide mineralization where:

- *Oxide Mineralization* – The oxide material could be processed utilizing modern heap leach, run of mine, processing technology. Zones of oxidation have been interpreted from drill chip logging by experienced geologists
- *Sulphide Mineralization* – The sulphide mineralization at Lincoln Hill is generally characterized as pyritic where the gold is associated with the mineral pyrite. It is assumed that additional processing, in addition to run of mine, would be necessary to recover gold from this mineralization.

There were a total of 5,495 three-metre-length composites used in the estimation of gold and 5,495 three-metre-length composites used in the estimation of silver. The results were calculated using Vulcan software and stored in a Vulcan block model. Inverse Distance estimation techniques were used to estimate mineralization throughout the deposit. Resources were classified as Measured, Indicated or Inferred based on the drilling density of the Lincoln Hill drilling data. These classifications meet the definitions as set forth in NI43-101.

Table 1.1 Lincoln Hill Measured and Indicated Resource at May 21, 2014

		Lincoln Hill Measured and Indicated Resources									
	Cutoff	Measured					Indicated				
	Grade	Tonnes	Grade	Ounces	Grade	Ounces	Tonnes	Grade	Ounces	Grade	Ounces
	Au g/t	(X1,000)	Au g/t	Au (x1,000)	Ag g/t	Ag	(X1,000)	Au g/t	Au (x1,000)	Ag g/t	Ag
Oxide	0.10	3,805	0.42	51	11.01	1,347	19,673	0.37	234	9.35	5,914
Sulfide	0.20	406	0.50	7	18.81	246	5,427	0.41	72	15.71	2,741
Total		**4,211**	**0.43**	**58**	**11.76**	**1,592**	**25,100**	**0.38**	**306**	**10.73**	**8,655**

Table 1.2 Lincoln Hill Inferred Resource at May 21, 2014

	Lincoln Hill Inferred Resources					
	Cutoff Grade Au g/t	Inferred				
		Tonnes (X1,000)	Grade Au g/t	Ounces Au	Grade Ag g/t	Ounces Ag
Oxide	0.10	8,802	0.26	74	7.87	2,227
Sulfide	0.20	12,020	0.47	182	15.36	5,936
Total		**20,822**	**0.38**	**255**	**12.19**	**8,163**

1.5 MINE PLANNING

The mineral resources have gold and silver grades that could support an open pit mining heap leach processing operation. Heap leaching is an economically viable processing method in the current metal price environment. This mining approach is the basis of the analysis and evaluation developed for the PEA.

A Preliminary Economic Assessment provides a basis to estimate project operating and capital costs and establish a projection of the potential mineable resource including measured, indicated and inferred categories as permitted under National Instrument 43-101. Whittle pit optimization was performed using estimates of operating costs typical of operating surface mines using heap leach processing in northern Nevada, and using estimates of metallurgical recovery based on test work performed on the Property. . The ultimate pit shell was determined using a gold selling price of $1,350 per ounce and a silver selling price of $22 per ounce. In-pit resources used for production scheduling are listed in Table 1.3.

The estimated strip ratio for the pit is 0.55 tonnes of uneconomic material for every 1 tonne of mineralized material processed.

The PEA incorporates inferred mineral resources which are considered too geologically speculative to have the economic considerations applied to them that would enable them to be categorized as mineral reserves. Therefore there can be no certainty that the estimates contained in the PEA will be realized.

Table 1.3 Potential Processed Material

Classification	Mineralized Material (Tonnes X1,000)	Gold Grade g/t	Gold Ounces (X1,000)	Silver Grade g/t	Silver Ounces (X1,000)
Measured	1,567	0.62	31	12.9	648
Indicated	5,250	0.69	116	13.7	2,311
Measured & Indicated	6817	0.67	148	13.5	2,958
Inferred	1,092	0.53	19	23.3	819

1.6 METALLURGY

Based on bottle roll testing and capital economic considerations, a run of mine (ROM) heap leach process has been selected as the best processing method. A heap leach pad, capable of holding 8 M Tonnes of leach material at a loading rate of 4.4 K Tonnes per day, will be the basis for recovering metals from the Property. ROM gold recovery is expected at 64% of total placed and silver at 59% of total placed. Recovery is expected over two years from date placed on a declining curve. The pad will remain open for two years from final leach material placed before final reclamation begins.

1.7 CAPITAL COSTS

Capital costs were developed based on scaling costs from similar facilities for production rates and from design basis assumptions including a contractor operated mining fleet. The estimated life of mine capital costs for the base case are summarized in Table 1.4:

Table 1.4 Life of Mine Estimated Capital Costs

Description	US$(millions)
Initial Capital	14.2
Working Capital	4.0
Indirect, Sustaining, Owner and Royalties	12.0
Total	**30.2**

1.8 OPERATING COSTS

Operating cost assumptions were based on similar scale surface mining operations using heap leach processing in northern Nevada, and process cost estimates for key consumables based on the available metallurgical test data, power consumption data and prevailing costs for key materials in similar Nevada mining operations. Operating cost assumptions per tonne of material processed are summarized as follows:

Table 1.5 Unit Operating Costs

Cost Category	US$ (Per Tonne Processed)
Waste Mining Cost	$2.50
Ore Mining Cost	$3.10
Heap Leach Processing	$3.60
General and Administrative	$1.50
Reclamation	$0.76
Total	**$11.46**

1.9 ECONOMIC ANALYSIS

MMC chose US$1350 for gold and US$22 for silver as the base case economic scenario. The base case pre-tax economic results for the metal price assumptions are as follows:

Table 1.6 Pre Tax Projected Economic Results (US$)

Cost Category	US$
Gold Price per Ounce	$1350
Silver Price per Ounce	$22
Net Cash Flow	$78.4 million
NPV @ 5% Discount Rate	$64.2 million
Internal Rate of Return	76.5%
Operating Costs per Ounce of Gold Equivalent Produced (Life-of-Mine)	$575
Total Costs per Ounce of Gold Equivalent Produced (Includes all Capital)	$759

1.10 INFRASTRUCTURE

There are currently no facilities of any kind at Lincoln Hill. Lincoln Hill is accessible from Lovelock, Nevada and near Highway Interstate 80. The Project is accessed via the Lovelock-Unionville Road, the same road used to access Coeur Mining's Rochester Mine. There is ample electric power available. Water is available. Two nearby operations, Perching Gold's Relief Canyon and the Coeur Rochester Mine are currently in operation. With proper permitting, Lincoln Hill could become an operating Nevada mine. Lovelock, Winnemucca, Fallon and Fernley are close enough to support an experienced mining staff.

1.11 CONCLUSIONS

Rye Patch has invested considerable effort, in the advancement of the Lincoln Hill Property through drilling, permitting, technical and metallurgical evaluations, internally and with the assistance of reputable consulting firms. This evaluation indicates a strong positive performance of a heap leaching facility at Lincoln Hill at the current metal price environment. The project performance is most sensitive to gold price and gold recovery. Metallurgical data to this point indicates economic extraction of metals is not complicated.

Exploration potential adjacent to the project and within other Rye Patch controlled claims is positive with some untested targets.

The project economics suggest that this is a project that can be put into production for a capital investment of approximately US $26.3 million and being paid back within 2 years of startup. Lincoln hill is a project that warrants a more advanced review than a scoping study. Measured and Indicated Mineralization has been sufficiently identified and should be used as the basis of a Preliminary Feasibility Study.

1.12 RECOMMENDATIONS

1.12.1 PROJECT DEVELOPMENT

MMC recommends that Rye Patch should engage the services of a reputable consulting firm in the advancement of the project to the preliminary feasibility level. Lincoln Hill represents a resource which includes Measured and Indicated resources. MMC recommends the following plans should be investigated to develop a better knowledge of the deposit economic criteria.

1.12.1.1 OPEN PIT GEOTECHNICAL PROGRAM

The open pit design parameters presented in Section 16 have been developed with only limited geotechnical data on the rock mass and observations of neighboring mining operations. The methods used to estimate these parameters are reasonable for this preliminary economic assessment. It is recommended that the following activities be conducted to advance the design to the feasibility design level:

- Drill geotechnical core-holes to characterize the rock mass and collect samples for laboratory testing;
- Perform slope stability analysis of pit designs including:
    - Kinematic stability of benches,
    - Numerical analysis of global pit slopes that includes pit interaction with underground, and
    - Rock fall assessment of berms and set-back distances.

1.12.1.2 METALLURGY AND PROCESS DESIGN

Metallurgical studies have only been performed at a scoping level. The next phase of metallurgical investigation should include further metallurgical testing and detailed studies to more thoroughly evaluate the optimum process flow sheet and required process parameters. A metallurgical testing program that includes column leach tests will be a major portion of the test work campaign.

1.12.1.3 INFRASTRUCTURE

For a feasibility study, MMC recommends Rye Patch begin:

- Transportation study for road enhancements and logistics from Lovelock to Lincoln Hill;
- Water study and site water balance; and
- Power line study and communication with local power suppliers.

1.13 RECOMMENDATION COSTS

MMC estimates the proposed advancement programs will cost approximately $1.7 million as follows:

Table 1.7 Recommended Advancement Costs

Budget Item	Description	Cost (1000's)
Geotechnical Studies and Drilling	Conduct infill drilling	US$600
Geology	Resource Model Updates	US$75
Geotechnical, Groundwater Hydrology and Leach Pad	Field and engineering work for preliminary feasibility study	US$450
Mining, Metallurgy and Economics	OP Mine Planning, Cost Estimation and Reserves	US$75
Metallurgical test work	Continue to feasibility level	US$200
Other	Environmental, Social, Archeological, Permitting	US$300
Total		**US$1,700**

2 INTRODUCTION AND TERMS OF REFERENCE

2.1 PURPOSE OF TECHNICAL REPORT

At the request of Mr. William Howald, President and CEO, Rye Patch Gold Corp. (Rye Patch), this technical report has been prepared by Metal Mining Consultants Inc. (MMC) on the Lincoln Hill property (Lincoln Hill), Pershing County, Nevada. The purpose of this report is to provide Rye Patch and its investors with an independent opinion on the technical and economic aspects and mineral resources at Lincoln Hill. This report conforms to the standards specified in Canadian Securities Administrators' National Instrument 43-101, Companion Policy 43-101CP and Form 43-101F. The information in the report is current as of May 21, 2014.

Rye Patch US acquired Lincoln Hill in 2007 based on the geological setting and its strategic location near their recent gold discoveries at Willard, approximately 6 km to the west.

The work completed by Rye Patch US, along with historical data, forms the basis of this report. Some of the historical information was generated before the use of NI 43-101 reports and therefore does not comply with all of the requirements.

This report describes the property economic potential, geology, mineralization, exploration activities and exploration potential based on compilations of published and unpublished data and maps, geological reports and a field examination by the author. The author has been provided documents, maps, reports and analytical results by Rye Patch US. This report is based on the information provided, field observations and the author's familiarity with mineral occurrences and deposits in the Great Basin and worldwide. All references are cited at the end of the report in Section 27, References.

The authors visited Lincoln Hill on February 4, 2014 accompanied by Bill Howald and Radu Conelea, Rye Patch. This report was prepared by Scott E. Wilson, MMC, and the author has participated in all aspects of this report. There is no affiliation between Mr. Wilson, Rye Patch and Rye Patch US except that of independent consultant/client relationship.

2.2 QUALIFICATIONS

The Consultants preparing this technical report are specialists in the fields of geology, exploration, mineral resource and mineral reserve estimation and classification, surface and underground mining, environmental permitting, metallurgical testing, mineral processing, processing design, capital and operating cost estimation, and mineral economics.

None of the Consultants or any associates employed in the preparation of this report has any beneficial interest in Rye Patch Gold. The Consultants are not insiders, associates, or affiliates of Rye Patch Gold. The results of this Technical Report are not dependent upon any prior agreements concerning the conclusions to be reached, nor are there any undisclosed understandings concerning any future business dealings between Rye Patch Gold and the Consultants. The Consultants are being paid a fee for their work in accordance with normal professional consulting practice.

The following authors, by virtue of their education, experience and professional association, are considered Qualified Persons (QP) as defined in the NI 43-101 standard, for this report, and are members in good standing of appropriate professional institutions.

- Mr. William Pennstrom
- Mr. Scott E. Wilson

2.3 TERMS OF REFERENCE

The report fulfills the requirements of Rye Patch to list a publically traded company in Canada. The reader of this report can rely on its contents to represent an accurate assessment of the technical information in regards to Rye Patch US's Lincoln Hill. Note: All lengths are reported in metres (m) unless specified otherwise.

2.3.1 ABBREVIATIONS

m	Meter(s)
km	Kilometer(s)
g/t	Grams / tonne
oz	ounces
au	gold
ag	silver
cu	copper
zn	zinc
pb	lead
AA	atomic absorption
AuEq	gold equivalent
AOI	Area of Influence
AMR	Advanced Mineral Royalties
BLM	United States Bureau of Land Management
CFR	Code of Federal Regulations (U.S. Federal Code
CIM	Canadian Institute of Mining, Metallurgy and Petroleum Engineers
FA	Fire Assay with Atomic Absorption Finish
GPS	Global Positioning System
ICP	Inductively Coupled Plasma (Geochemical analytical method)
MDBM	Mount Diablo Base Meridian

NMC#	Nevada Mining Claim Number
NSR	Net Smelter return
RQD	Rock quality designation

2.4 CORPORATE RELATIONSHIPS

Rye Patch Gold Corp. (Rye Patch) is a British Columbia Corporation, and Rye Patch Gold US Inc. (Rye Patch US) is a Nevada Corporation. Both were formed in 2006 and Rye Patch US is the U.S. operating subsidiary of Rye Patch.

Rye Patch requested the completion of this technical report. When Rye Patch is referenced in this report, it refers to both Rye Patch and Rye Patch US. The individual company names will be referenced when needed for clarity.

2.5 UNITS OF MEASURE

All units of measurement used in this report are metric (English) unless otherwise stated. Currencies are expressed in US dollars. These are the units used by Rye Patch. Historical grade and tonnage is reported as originally published. Gold grades are reported as referenced and conversion factors are listed below. Location coordinates are expressed in Universal Transverse Mercator (UTM) grid coordinates, using the 1983 North American Datum (NAD83), Zone 11, Mount Diablo Base Meridian (MDBM).

Some of the conversion factors applicable to this report are:

Table 2.1 Analytical Values

	oz/tonne (opt)	gm/tonne (g/t)
1 ppm	0.03125	1
1 ppb	0.00003125	0.001

3 RELIANCE ON OTHER EXPERTS

Richard DeLong

Mr. Delong is the founder of Enviroscientists, Inc. a well-respected business known throughout the Northern Nevada mining community. Enviroscientists is a leading property development and permit acquisition firm that specializes in assisting natural resource development industries with property development needs, evaluation of environmental effects, and compliance with governing regulations. Mr. Delong is not a Qualified Person as defined by NI43-101. However, Mr. Delong's opinions regarding regulatory compliance are widely sought after and his recommendations are typically followed. The author knows of Mr. Delong's reputation, has relied on Mr. Delong's contributions to Section 21.

Tim George

As an employee of MMC, Mr. Tim George, Colorado Professional Engineer, was the largest contributor to Sections 16, 18, 19, 21 and 22. Mr. George is a Qualified Person per NI43-101. The author was involved with Mr. George's contributions to these sections. The author has relied upon Mr. George's input and takes responsibility for the contents of those sections.

4 PROPERTY DESCRIPTION AND LOCATION

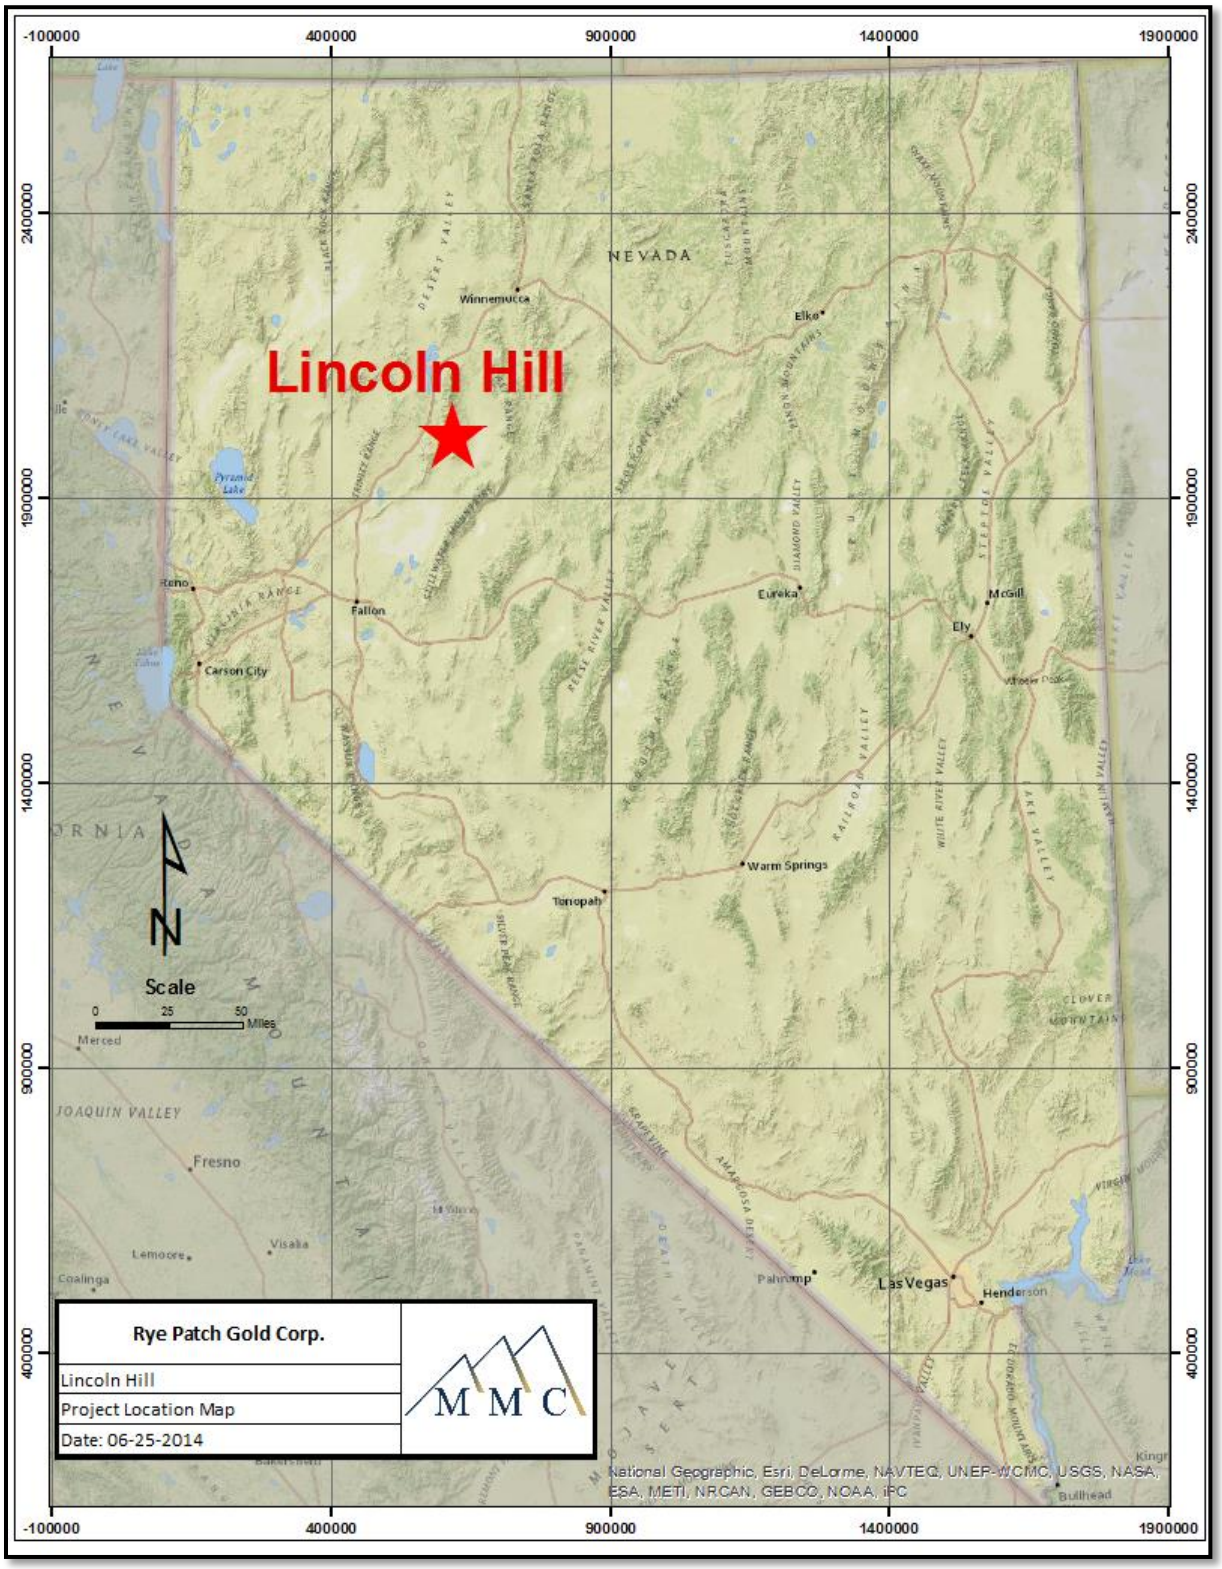
4.1 AREA AND LOCATION

Lincoln Hill is located in western Nevada, approximately 185 km (115 mi) northeast of Reno, Nevada (Figure 4.1). It is readily accessible from Interstate 80 (I-80) east of Lovelock, Nevada. From Lovelock, travel east on I-80 for approximately 37 km (23 mi), and turn southeast on the paved road towards the Humboldt Range. Travel for 6.4 km (4 mi) and take the right fork (gravel road). Follow this gravel road through the historic town of Old Rochester and turn north (left) at 4.8 km (3 mi). Various dirt roads and tracks traverse Lincoln Hill and access is reasonably good. There is a locked gate at the patented claims. Topography is gentle to moderate and a mix of sagebrush and pinion-juniper forest is present. Snow cover can make access to portions of the property difficult from late November through April although operations, such as drilling, should be possible even in these months. The elevation at Lincoln Hill ranges from approximately 1585 to 2018 m (5200 to 6620 ft).

Lincoln Hill consists of 146 unpatented lode mining claims (2 “Kings Ransom” claims, 4 “King Tut” claims, 10 “LHL” claims, 16 “ALH” claims, 6 “WMC” claims, 1 “Rochester Bonanza” claim, 2 “Raven” claims, 41 “LY” claims, 16 “LYF” claims, 24 “GG” Claims, and 24 “LH” claims,) and 2 patented lode mining claims, Abe Lincoln #2 and Blue Bird, and they are shown in Figure 4.2. The claims are located in all or portions of sections 12 and 13, T28N, R33E, and sections 6, 7, 18 and 19, T28N, R34E, MDBM. The unpatented and patented lode mining claims which comprise Lincoln Hill are listed in Appendix A. The unpatented lode mining claims are administered by the BLM on federally owned lands.

The known gold and base metal mineralization occurs in small prospect pits in the southern and central portion of the property. This is a historic mining area and has been explored extensively since the late 1800s.

Figure 4.1 Location Map of Lincoln Hill, Pershing County, Nevada



4.2 CLAIMS AND AGREEMENTS

Rye Patch US has entered into three exploration agreements and staked 81 claims at Lincoln Hill.

On November 7, 2007, Rye Patch US signed the Lincoln Hill Area Lease with an Option to Purchase Agreement with Mountain Gold Exploration, Inc. (MGE) and Lane Griffin (LG) (the MGE/LG Agreement). There are 3434 unpatented and 1 patented lode mining claims included in the MEG/LG Agreement (Appendix A). The schedule of minimum advance royalty payments due to MGE/LG are shown in Table 4.1. The term of the agreement is 20 years with auto-renewal and MGE/LG retains a 4% NSR. Rye Patch US can buy down the royalty for $1,000,000 for the first percent within 5 years and another percentage within 7 years for $3,000,000. There is an underlying lease, the Fialdini-Mahar Lease and Work Commitment, and Rye Patch has assumed these work commitments (

Table 4.2). The Area of Interest (AOI) is described as T28N, R33E, Sections 12, 13 and N1/2 24, T28N, R34E, Sections 7, 18 and N1/2 19, W1/2 8, W1/2 20. MEG and LG reserve the right to collect mineral specimens, without hindering any exploration or mining activities. The AOI only pertains to locatable ground staked by Rye Patch at the time and does not apply to any pre-existing claims.

Rye Patch Gold US Inc. located LY 87 to LY 127 unpatented lode mining claims in October 2006. A total of 41 LY unpatented lode mining claims are part of the Lincoln Hill project, and these claims are located in T28N, R34E, Section 7, and the western half of Section 18, MDB&M. The long axis of the claims are orientated north-south.

On September 8, 2009, Rye Patch US entered into an agreement for the Sale and Purchase of Unpatented Mining Claims (Walker Agreement) and a Warranty Deed with Reserved Royalty with Robert Walker (Walker). These documents include 3 unpatented lode mining claims (Appendix A) and reserve a 4% NSR to Walker, which can be bought down for $100,000 for each percentage. Rye Patch has the first right of refusal if Walker decides to sell his royalty interest. The total purchase price is $41,000 and the payment schedule is shown in Table 4.3. The final payment was made in September 2013.

In October 2011, Rye Patch US entered into a lease agreement with Nevada Land and Resource Company, LLC for three parcels of land located immediately adjacent to the Lincoln Hill property. The leased parcels give Rye Patch surface access to and from drilling sites on its Lincoln Hill project. The leased lands are located in T28N, R33E, Section 13, and T28N, R34E, Section 7, MDB&M. The Section 13 lease covers almost 395 acres while the Section 7 lease covers 120 acres. Rye Patch pays $18.46 per acre for the first five years of the lease, and $19.43 per acre starting in year six to keep the lease in affect. Rye Patch may terminate any or all of the parcels by giving 30 days' notice prior to the anniversary of the lease.

In January 2012, Rye Patch US acquired, through staking, 24 unpatented lode mining claims immediately adjacent to the Lincoln Hill property. Claims GG1 through GG 23 were staked in December 2011, and GG24 was staked in January 2012. The new GG claims were staked on open locatable ground located

between Barrick's Spring Valley land holdings and Rye Patch US's Lincoln Hill project in T28N, R35E, Section W ½ 8 and N ½ 17. The 24 unpatented lode claims were staked covering historic mine workings on Golden Gate Hill. The area has similar geology to Lincoln Hill with historic workings indicating the presence of elevated silver and gold mineralization along structural zones.

In late January and February 2012, Rye Patch staked the LYF1 to LYF16 unpatented lode mining claims. The LYF9 to LYF16 claims cover fractions of open ground within the Lincoln Hill resource area and are located in T28N, R33E, Sections 12, 13, and 24, and T28N, R34E, Section 18. The LYF1 to LYF8 claims cover open ground located in T28N, R33E, Section 12.

In October 2011, a group of LH unpatented lode claims were located immediately south and adjacent to the Lincoln Hill project. These LH claims became part of a legal dispute between Rye Patch Gold US Inc. and Coeur Rochester Mining. The legal dispute was resolve in June of 2013, and Rye Patch Gold US Inc. retained title and interest to certain LH claims totaling twenty-four unpatented lode claims named LH 136 to LH 156, LH 209, LH 211, and LH 501. In addition, Coeur Rochester granted, conveyed, and transferred title and interest of the Blue Bird patent, Patent No. 604728, Mineral Survey No. 4252, located in the SW1/4 of Section 18, T.28N., R.34E, to Rye Patch Gold US Inc.

The preceding discussion on land status describes the claims and agreement as reviewed by the author, as of September 17, 2012. No land title work has been completed on the property, although a "Status Report" was completed in 2012 (Perry, 2012) on the unpatented lode mining claim included in the MGE/LG agreement. The author reviewed the Agreements, the annual documents filed with the BLM and Pershing County. The author is not a Registered Landman.

The area covered by the MGE/LG Agreement includes a total of 34 unpatented and 1 patented lode mining claims which cover approximately 536 hectares (1325 acres). Table 4.1 shows the Lincoln Hill project area with mineral claim locations.

Table 4.1 MGE/LG Agreement, Minimum Advance Royalty Payment Schedule

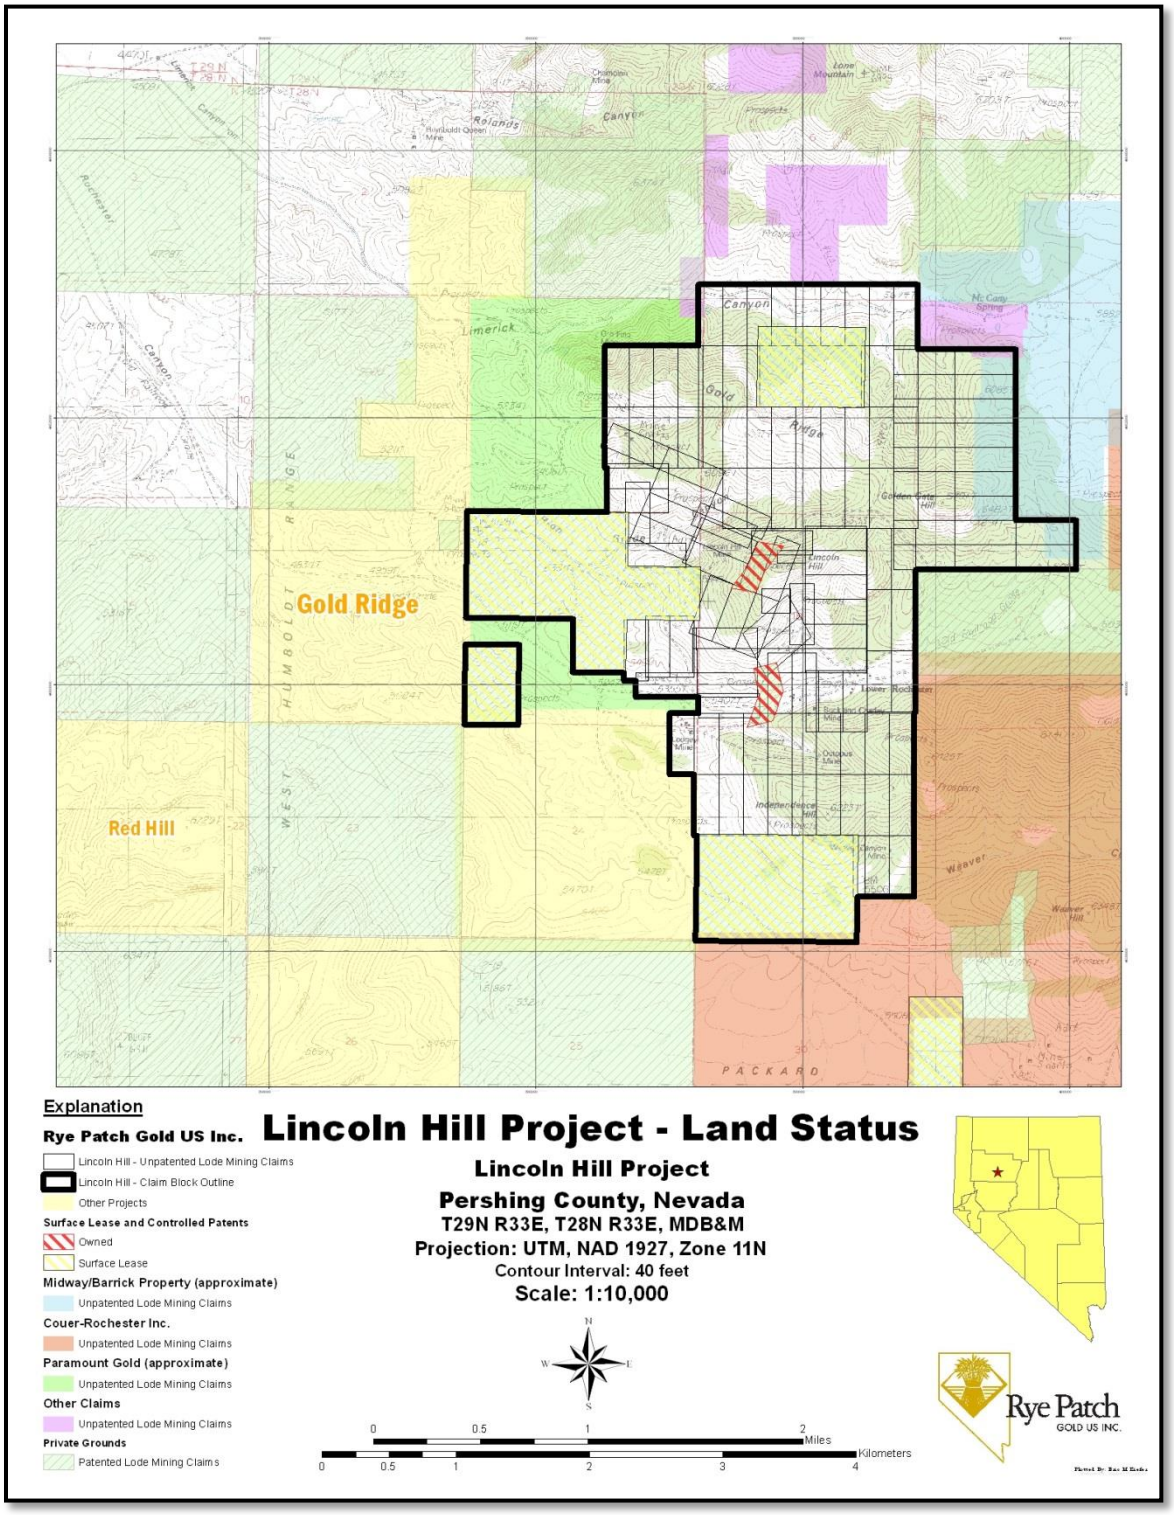
4th Anniversary	$15,500	Complete

Figure 4.2 Land Status, Lincoln Hill Property, Pershing County, Nevada



Map From Rye Patch US

4.3 ENVIRONMENTAL LIABILITY

There has been no Environmental Liability study on Lincoln Hill. The only environmental issues apparent during the author's brief field visit are numerous small historic prospect pits and dumps. Rye Patch US has completed a drilling program as described in Section 10 and have permits in place as described in Section 4.6.

The author is not a Qualified Person in environmental issues and therefore these statements should not be taken as a professional opinion. A qualified expert should be consulted if a professional Environmental Report is required.

4.4 CLAIM MAINTENANCE FEES

The 2013 Maintenance Fee Payments in the amount of $19,880.00 was paid for the 142 unpatented lode claims subject to the Lincoln Hill Project; (Walker Agreement (3 claims), Mountain Gold Claims LLC Ser1 / Lane Griffin Agreement (34 claims) and Rye Patch owns claims (105 claims). Dates of filing with the Nevada State BLM Office are listed in Table 4.4. The Federal mining claim maintenance fees must be paid in advance of the annual assessment year on or before September 1, 2013, and September 1 of each succeeding year. The failure of the owner of the claims to properly and timely pay the BLM annual mining claim maintenance fees will cause the forfeiture of the claims.

Table 4.4 2013 Claim Maintenance Fees

2013 BLM Claim Maintenance Fees					
Claimant	**Claims**	**Total Claims**	**Paid BLM**	**Total Paid**	**BLM Receipt No.**
Walker	Raven et al	3	7/29/2013	$420.00	2841424
MGCLLC/LG	Kings et al	34	7/29/2013	$4,760.00	2841463

Rye Patch	LH 136-156, 209, 211, 501	24	7/29/2013	$3,360.00	2841438

4.5 FEES DUE TO PERSHING COUNTY, NEVADA

Annual filings fees in the amount of $1,533.00 were paid to the Pershing County Recorder for the 142 unpatented claims subject to the Lincoln Hill Project. Under Nevada law, the owner of the claims must record in the office of the recorder a notice of intent to hold the claim for each assessment year. The Notice of intent must be recorded on or before November 1 of each year. Notices of Intent to Hold Mining Claims for the Lincoln Hill Project were timely filed with the Pershing County Recorder's Office (Table 4.5).

Table 4.5 2013 Annual Filing Fees

2013 Pershing County Claim Maintenance Fees					
Claimant		**Total Claims**	**Filed County**	**Total Paid**	**County Document No.**
Walker	Raven et al	3	10/14/2013	$38.50	485726

Rye Patch	LH 136-156, 209, 211, 501	24	10/14/2013	$259.00	485730

4.6 PERMITS

On May 20, 2008, Rye Patch US submitted a Notice level application to drill 14 holes and disturb 2.82 acres at Lincoln Hill. The BLM acknowledged the Notice as complete and assigned the serial number N-85224 on June 9, 2008. The reclamation bond for the Original Notice was obligated at $24,333. On September 14, 2009, Notice Revision #1 was submitted to the BLM which included 4.85 acres of surface disturbance and an adjusted reclamation bond amount of $23,362. The BLM authorized Revision #1 of the Notice and the adjusted bond amount on October 9, 2009. Notice Revision #2 was submitted to the BLM on August 4, 2010 which included a total of 4.88 acres of surface disturbance and an adjusted bond amount of $13,637. The BLM authorized Notice Revision #2 on August 24, 2010.

The Federal Regulations that govern the exploration activities and surface disturbance at Lincoln Hill are 43 CFR 3715, 3802, 3809 and 3814 (Code of Federal Regulations). A Notice level operation is one which disturbs less than 5 acres. If Rye Patch plans to exceed 5 acres of surface disturbance, a Plan of Operations/Nevada Reclamation Permit and Environmental Assessment will be required along with a recalculated reclamation cost estimate.

Currently Rye Patch US has reclaimed 4.6 acres of disturbance from their 2011 drilling campaign and is awaiting approval from the BLM for the reclaimed areas to be released before construction of new drill pads and roads can be executed. Figure 4.3 shows these areas of disturbance pending BLM approval for release. On August 2013, after a field inspection BLM released 1.45 acres of disturbance. On December 16, 2013, Rye Patch Gold US Inc submitted a Notice level application, revision #4 for 11 drill sites and new disturbance of 1.79 acres. The total disturbance after the notice is 4.94 acres and the project is currently bonded for $ 21,020.00.

Map From Rye Patch US Ronaldo da Silva

5 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

5.1 ACCESS AND INFRASTRUCTURE

Lincoln Hill is located in Pershing County, Nevada, approximately 185 km (115 mi) east of Reno, Nevada. It is readily accessible from Interstate 80 (I-80) east of Lovelock, Nevada. From Lovelock, travel east on I-80 for approximately 22.5 km (14 mi), and turn southeast on the paved road (Rochester Mine Road) towards the Humboldt Range. Travel for approximately 6.5 km (4 mi) and take turn onto the good dirt road and travel for another 4.8 km (3 miles), through the historic town of Old Rochester, and to the southern end of the Lincoln Hill property. Various dirt roads and tracks traverse Lincoln Hill and access is reasonably good. There is a locked gate at the patented claims. Topography is gentle to moderate and a mix of sagebrush and pinion-juniper forest is present. Snow cover can make access to portions of the property difficult from late November through April although operations, such as drilling, should be possible even in these months.

Lovelock, Nevada, a town of approximately 2400 population is the closest town with services. The main Union Pacific Railroad is less than ten miles from the property and I-80 is just 4 miles southwest. Power is available <10 km (6 mi) to the west at I-80 or at the nearby Rochester Mine. Power for exploration activities are generally through portable generators. Water for exploration activities is purchased from nearby ranches. Personnel are available in Lovelock (37 km to the west on I-80) or Winnemucca (113 km to the east on I-80).

5.2 PHYSIOGRAPHY

The Lincoln Hill property lies in the west-central part of the Great Basin part of the Basin and Range Physiographic Province. The Great Basin is characterized by north-northeast trending mountain ranges separated by wide flat valleys. Numerous small drainages are all dry, except briefly during the spring or seldom heavy rainfall events. Lincoln Hill is in the central part of the Humboldt Range. The Humboldt Range trends approximately north and is bounded by the Humboldt River and the Upper Valley to the west and the Buena Vista Valley to the east. Lincoln Hill ranges in elevation from approximately 1585 to 2018 meters (5300 to 6620 feet).

There is adequate gently sloping ground on the western portion of the property for any waste dumps, leach pads, processing facilities or offices.

5.3 CLIMATE

Nevada is a high desert state and the climate at Lincoln Hill is semi-arid to moderate, which is typical of the northern Great Basin. Annual rainfall in the area ranges from approximately 5-6 in the valleys to approximately 20 inches in the mountains. Lincoln Hill ranges in elevation and therefore receives between 24.5 and 38.1 cm (10-15 in) of precipitation, with most occurring in the winter months. Evapotranspiration exceeds precipitation. The soils are classified as “northern gray desert” with plants

including sagebrush, pinon, juniper, greasewood, rabbit brush and mountain mahogany. The higher elevations are more densely vegetated than the lower elevations.

6 HISTORY

The Lincoln Hill property is located in the Rochester mining district, in the southwest flank of the Humboldt Range. The Spring Valley mining district is to the east and north and the Sacramento district is to the west. The Rochester district has produced more silver than any other district in Pershing County (Johnson, 1977). The earliest reports on the geology of the Rochester mining district are Schrader (1913) and Knopf (1924) and they contain discussion of the gold and silver mineralization at Lincoln Hill. A summary of the production from the Rochester district is shown in Table 6.1. The Lincoln Hill production is included in these totals.

The following discussion on the Rochester district history is from Johnson (1977). During the 1860s there was prospecting across the entire Humboldt Range. In 1905 prospects were located in the area now called the Rochester Mine and by 1912 rich silver deposits were discovered. The silver mineralization is disseminated at Rochester and the deposits were difficult to define. The deposits were worked extensively from 1912-1929 at which time the Lincoln Hill area was producing gold. From 1931 to 1966 there were some active mines in the district but the production was lower than the earlier years.

There are no specific production figures for Lincoln Hill although gold and silver have been mined from the hill through the 1980s. The Lincoln Hill gold and silver production is included in the Rochester district (Table 6.1). Approximately 915 m (3000 ft) of underground workings and the majority are dry and accessible. Numerous prospect pits and mine dumps occur along approximately 2134 m (7000 ft) of strike length.

Since 1980 two companies have conducted exploration activities at Lincoln Hill. This work was completed before the advent of NI 43-101 regulations. During the 1980s, Coeur Exploration conducted surface exploration activities and drilled 8 RC holes into the upper eastern portion of the altered and mineralized zone. During 2001 and 2002, Newmont exploration completed geological mapping, surface and underground rock sampling and then drilled 8 RC holes. Newmont's drilling was primarily outside the main zones of surface alteration and mineralization and they appeared to be searching for lateral and vertical extensions of the mineralizing system. The historic drill holes are shown in Table 6.2 and relevant gold results from these holes are shown in Section 10, Drilling (Table 10.1 and Table 10.2). The location and hole traces for the historic drill holes at Lincoln Hill are shown below in Figure 6.1.

Rye Patch US signed an agreement on Lincoln Hill in 2007 and has completed geologic mapping, surface rock sampling and four drill campaigns. Their work program is described in the following sections. Lincoln Hill lies within the newly named Oreana Trend, an alignment of gold and silver deposits and occurrences from Wilco to Spring Valley.

Table 6.1 Production from the Rochester District

	Au oz	Ag oz
1912-1929	74,353	8,683,280
1931-1951	3665	192,370
1951-1986	not reported	not reported

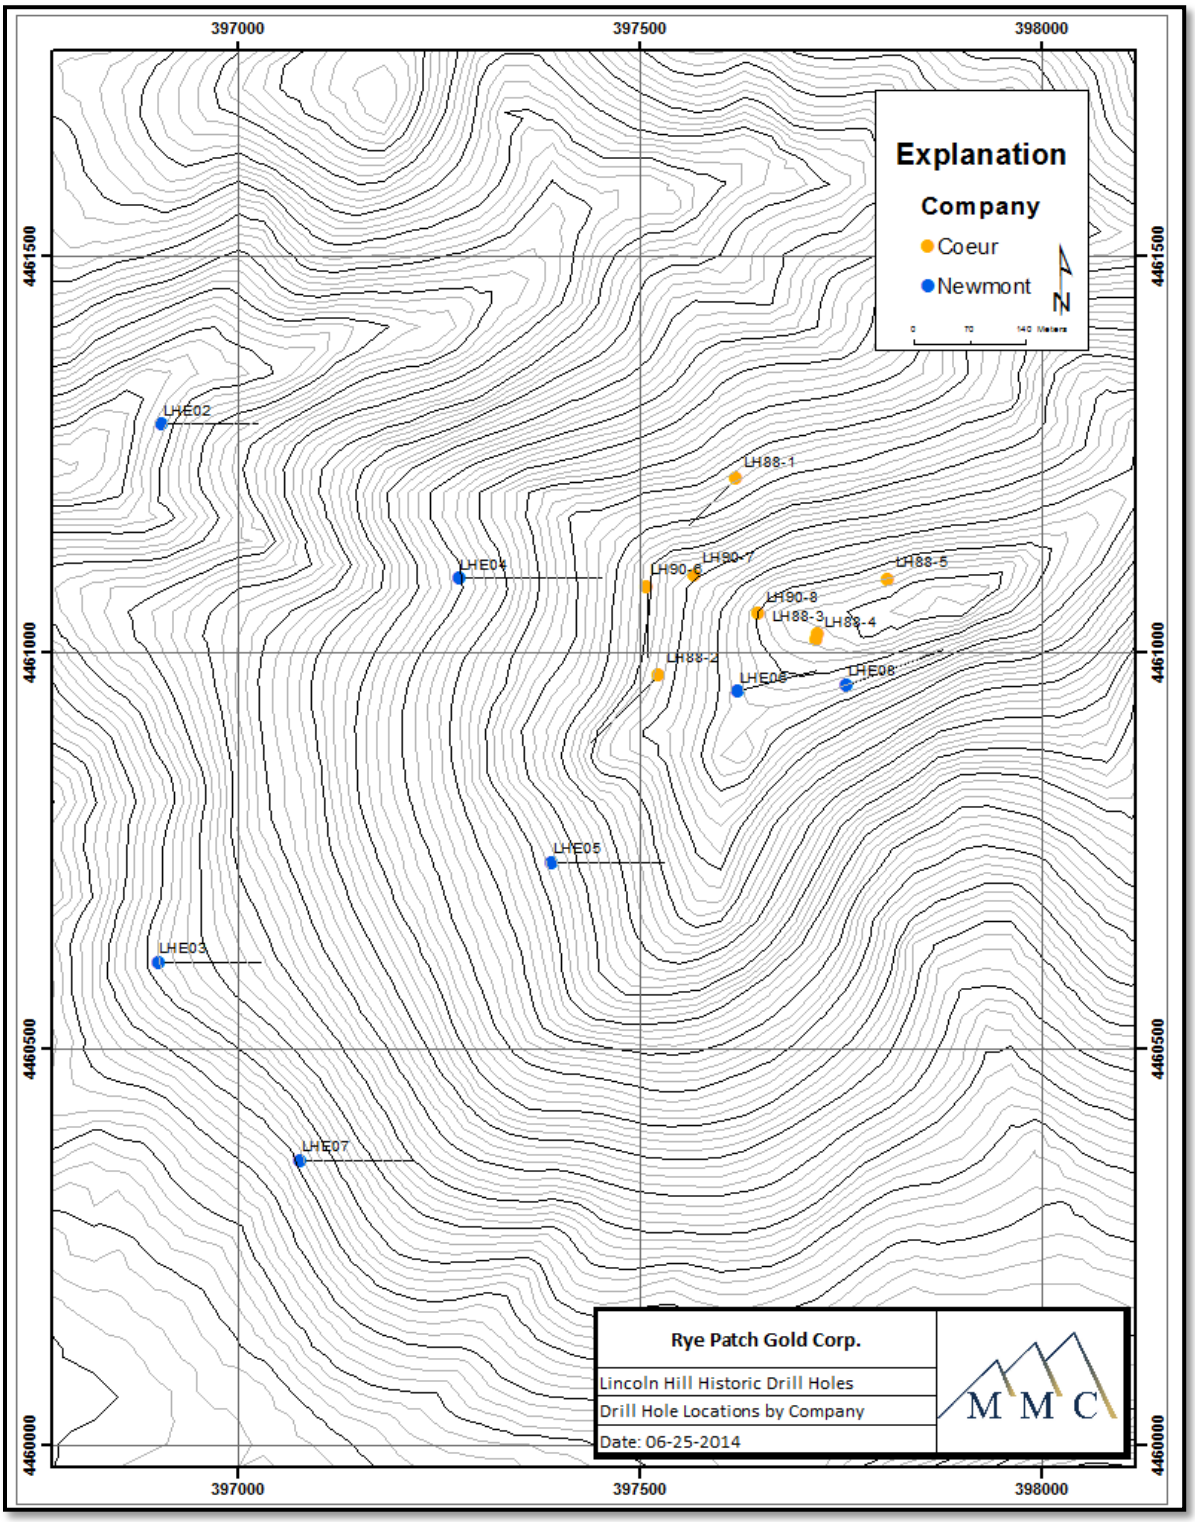
Figure 6.1 Lincoln Hill Historic Drill Hole Locations



7 GEOLOGICAL SETTING AND MINERALIZATION

7.1 REGIONAL GEOLOGY

Lincoln Hill lies in the west-central portion of the Great Basin part of the Basin and Range Physiographic Province. The Great Basin is characterized by north to northeast trending ranges separated by wide flat valleys. In this part of Nevada, the ranges are generally made up of Mesozoic and Tertiary volcanic and sedimentary rocks. The Great Basin is characterized by internal drainage, high heat flow and a sustained period of episodic magmatism. The regional geologic setting is shown in Figure 7.1. Lincoln Hill lies in the Rochester Mining District, which has had a history of silver and gold production from 1912 to the present.

Paleozoic rocks of the Great Basin are primarily sedimentary rocks deposited along a continental margin. The early Paleozoic was a relatively geologically quiet time in the Great Basin, with slow eastward advancement of the shoreline. The Antler Orogeny deformation began in the Devonian and lasted through the mid-Mississippian. This deformation caused uplift to the west later waning of sedimentation. The siliciclastic and carbonate coeval assemblages have been juxtaposed by thrusting, placing the siliciclastic rocks over the carbonate sequence. The Sonoma Orogeny again thrust siliciclastic, turbidites and volcanic rocks over the Antler assemblages and carbonates of the eastern assemblage. The Triassic-Jurassic boundary is marked by clean sandstone.

The Mesozoic sedimentary rocks have been classified into five major depositional groups of strata (Johnson, 1977). The groups that are exposed in the Humboldt Range are the Koipato and Star Peak Groups. The Koipato is comprised of nonmarine volcanic and sedimentary rocks. Deposition of the Koipato was accompanied by faulting and tilting which caused its present distribution to be discontinuous across this portion of Pershing County. The Star Peak Group is comprised of limestones and dolostones, unconformably overlying the Koipato Group nonmarine rocks.

West of the Humboldt Range the rocks are primarily mid-upper Mesozoic and Tertiary volcanic, intrusive and sedimentary strata. The Laramide Orogeny was in Late Cretaceous to Early Cenozoic and by the Oligocene the major tectonic component had changed to extension and about 19Ma the characteristic “basin and range” was formed. These extensional normal and listric faults bound most of the north to northeast trending ranges of the Great Basin and cut the major Antler and Laramide structures. Igneous activity in early to mid-Cenozoic time is dominated by widespread volcanic deposits over much of central and western Nevada. By mid-Cenozoic volcanic ash, ash flows and ash flow tuffs from numerous vent areas cover the pre-Cenozoic age rocks. Following the extrusion of these large amounts of volcanic material, collapse formed the numerous circular calderas that occur across much of Nevada’s Great Basin.

In the Quaternary, Lake Lahontan, a large fresh water lake, was formed and covered most of central and western Nevada. Walker Lake, Pyramid Lake and several smaller lakes all exhibit internal drainage and are all that remain of the widespread Lake Lahontan.

7.2 LOCAL/PROPERTY GEOLOGY

The geology of this part of the Humboldt Range has been studied extensively because it has the most complete section of the Koipato Group and it has a long history of silver and gold production, primarily from the Rochester Mine. Figure 7.1 is the regional geologic map of the Lincoln Hill area. Figure 7.3 is the Lincoln Hill geologic map which is based on surface mapping in 2008 and 2009 by Pinto da Silva (2009).

The following description of the rocks exposed at Lincoln Hill, from oldest to youngest, is from the geologic mapping by Pinto da Silva (2009).

Mafic Unit – Composed of andesite lavas, lithic tuffs, ash flow tuffs, and crystal tuffs. It is light to dark green and mainly outcrops along the axis of the anticline located in the southern portion of Lincoln Hill. The crystal tuffs are distinctive with white millimeter long feldspar crystals in a fine grained matrix. The lithic tuffs have <=2 cm fragments of andesite.

Sedimentary Unit – Strongly silicified rocks that are only encountered in drilling. It marks the Rochester Rhyolite-Mafic Unit contact. It is a massive to weakly foliated, silicified, dark gray to black mudstone. Recent drilling suggests that the unit thickens to the north, to a maximum of 16.8 m (55 ft).

Koipato Group:

- **Rochester Rhyolite –** The Rochester Rhyolite hosts precious metal mineralization at Lincoln Hill and is divided into three sub units:
- **Basal Unit (600-700 feet) –** In outcrop it consists of intensely silicified, locally argillized, fine grained tuff. In core, the unit shows a more complex assemblage of volcanic rocks including, crystal tuffs, lapilli lithic tuffs and breccias. The crystal tuffs are comprised of rounded to euhedral, <= 2 mm broken white feldspar crystals that can be up to 60% of the rock. There are local interbedded lavas. The lapilli lithic tuffs consist of 1 mm to 4 cm diameter angular to rounded fragments of felsic volcanic rock with local chlorite. Mineralized breccias occur mainly along high angle faults and consist of 1-6 cm diameter fragments of felsic volcanic rocks and some quartz in a fine grained matrix with abundant limonite and hematite.
- **Intermediate Unit (100-300 feet) –** Fine gray, intensely argillized, sericitic, felsic tuffs with local well-developed foliation overprinting flow banding. Cataclastic and mylonitic foliation occur in places.
- **Upper Unit (<200 feet) –** Host to the ornamental dumortierite-rich rock. Andalusite, tourmaline and massive sericite occur in a strongly pervasively silicified felsic rock. Silicification is intense and pervasive and is intersected by discordant quartz-black tourmaline veins and stockwork, which can host anomalous gold mineralization.
- **Lamprophyre Dikes –** Several lamprophyre dikes cut the Rochester rhyolite. They are massive, fine grained to aphanitic and range from 1- 7.6 m (3-25 ft) thick. They are oriented N30-40W and dip 60-85 degrees NE. Argillized in places and can have a strong stockwork along the

contact with the host Rochester Rhyolite. Au+Ag can occur along this Lamprophyre-Rochester contact. The Rochester Rhyolite is overlain by a massive dark gray limestone in the southwestern portion of the property. The limestone is locally cut by quartz veins or quartz stockwork.

Qal: Quaternary Alluvium fills the drainages**.**

The following discussion of the structure and alteration at Lincoln Hill is from Pinto da Silva and Howald (2009).

Lincoln Hill lies within the newly named Oreana Trend (Pinto da Silva and Howald, 2009). This mineralized corridor extends from the Willard/Colado (Wilco) area to the Spring Valley deposit. It is characterized by the alignment of recent and historic gold and silver deposits and occurrences. Additionally, the structures that host the mineralization at Wilco (the Willard and Colado deposits) correspond well with the N55E alignment of deposits in the Oreana Trend (Conelea and Howald, 2009).

Structurally, the district lies within a broad asymmetrical antiform that is cut by later north-trending faults. Coeur Rochester's Nenzel Hill silver deposit lies in the central portion of this fold and Lincoln Hill, along with several other mineral occurrences, are situated along the western limb of the fold. In the core of the Lincoln Hill mineralized area, the rock units are oriented E-W, dipping gently to south. NNW-SSE striking and SW dipping of the units is also a common feature at Lincoln Hill. During the extension of the district all rock units were faulted and tilted by NW and NE faults.

At Lincoln Hill, the Rochester Rhyolite is intensely altered over an extensive area with minimum dimensions of 5,000' long by 1,000' wide by 1,000' vertical. Silicification and argillization are the most conspicuous alteration and envelops most of the mineralization. Black tourmaline is also present occurring close to the mineralization as well as in a wide halo. Detailed surface and underground mapping has recognized two main gold and silver mineralized systems:

- A high-grade, coarse-gold-bearing quartz-tourmaline-sericite-clay altered stockwork-vein system is associated with N30º to 60ºW striking, altered lamprophyre dikes. High-grade gold mineralization occurs within and adjacent to the altered dikes that extends over 500 feet along strike. Gold mineralization associated with this part of the system averaged 7.5 opt gold from selective mining in the early 1900's.
- An additional later high-grade, coarse-gold, hematitic-clay altered tectonic fault-fracture system, which strikes N45°E, intersects and slightly offsets the lamprophyre dikes and associated gold-silver mineralization. These structural zones appear to have controlled the oxidation of earlier sulfide mineralization throughout large portions of the hill. Significant gold mineralization is associated with this part of the system.

Both of the northwest and northeast mineralized structural zones contain extensive, multiple stoped underground workings with numerous scattered prospect pits between the different stoped-mined zones. Minor placer gold deposits have been worked below Lincoln Hill in High Grade Canyon.

Low-grade gold and silver mineralization is associated with quartz veinlets oriented northwest to southeast, and a close association with pervasive silicification. This blanket-like mineralized zone starts at the surface and has been drilled to a depth of 500 feet.

Rye Patch US interprets the regional folding, foliation and mineralization to be related to several porphyry-style intrusions emplaced along the Oreana trend during the Miocene. The north-south and northwest structural zones contain diabase intrusions and lamprophye dikes that suggest deep crustal structures. These deep seated structural zones were important for the emplacement of the intrusive and as possible pathways for gold and silver mineralization.

Figure 7.1 Regional Geologic Map of Lincoln Hill and the Humboldt Range (From Johnson, 1977).

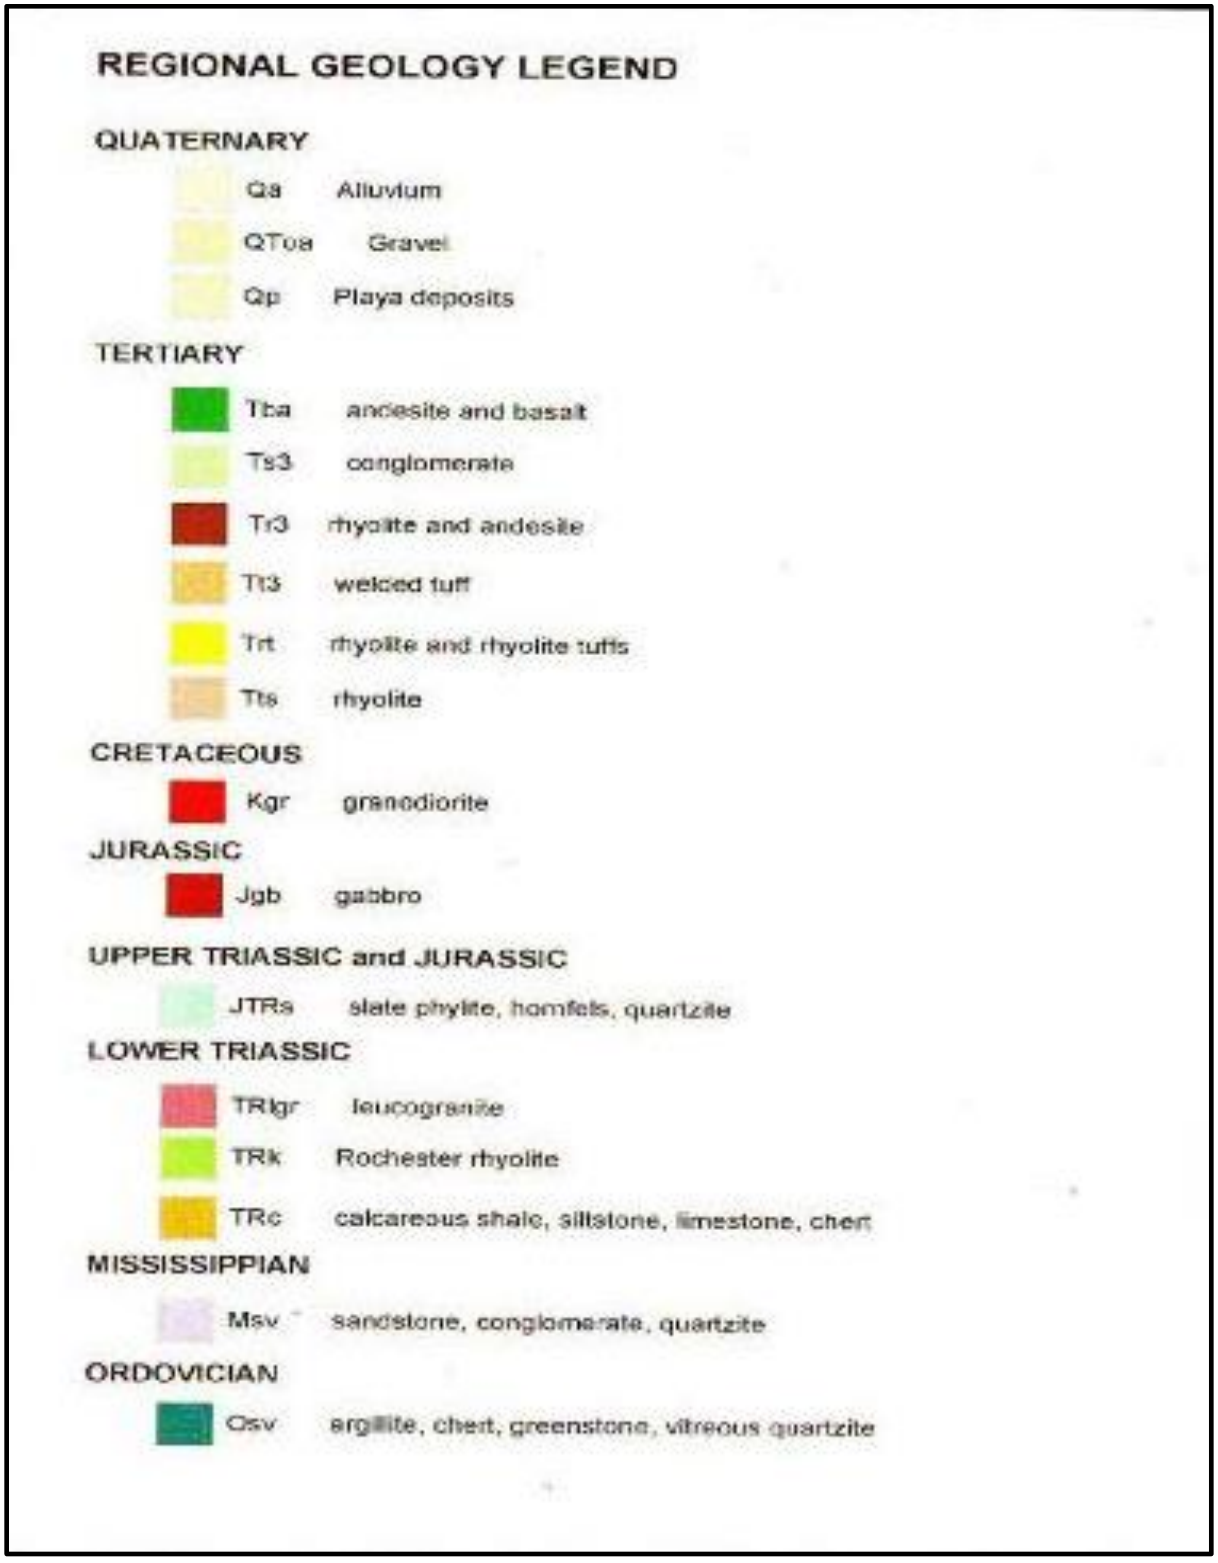

Figure 7.3 Geologic Map of Lincoln Hill

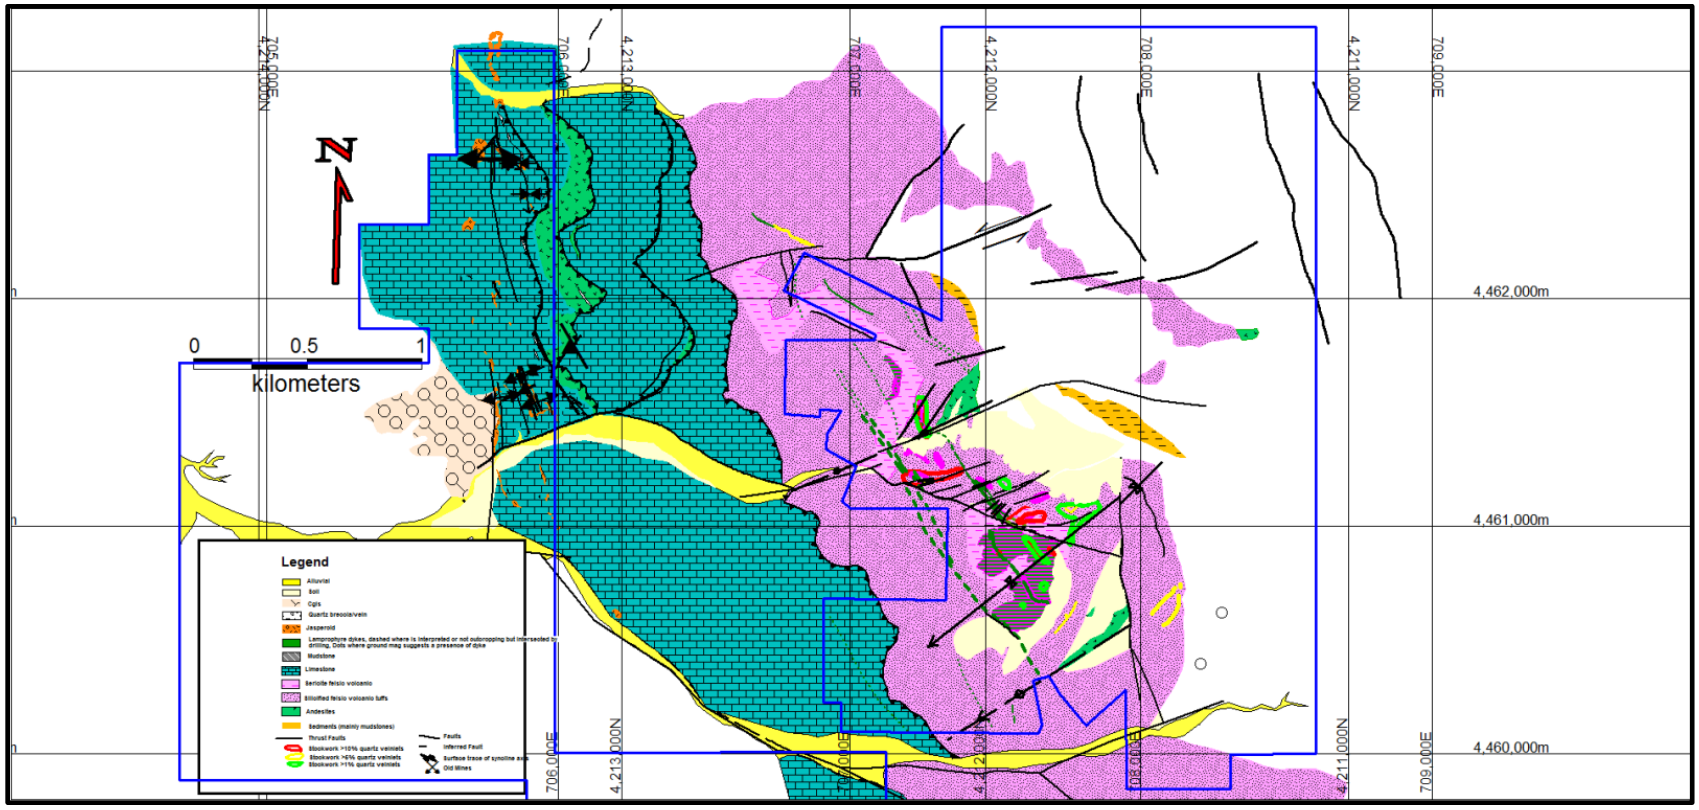


Map From Rye Patch US

7.3 MINERALIZATION

Lincoln Hill is in the Rochester mining district and has some characteristics in common with the bulk-tonnage Coeur Rochester Mine 3.2 km (2 miles) to the east and the recently expanded Spring Valley deposit 4.8 km (3 mi) to the northeast.

Gold occurs in several distinct "areas" at Lincoln Hill, as shown in Figure 7.4 (Main, Shaft, Lamprophyre, Flat, Washington, Jefferson, Lincoln Hill, Ouro Fino, Middle Dyke and Exploration). These "areas" were defined by Ronaldo Pinto da Silva, Rye Patch US geologist, during mapping, sampling and drilling at Lincoln Hill. The following are characteristics in common between the 5 zones.

- Silicification
  - Dense replacement silica
  - Quartz stockwork veins and veinlets
- Argillization outside the silicification
- Lack of pyrite
- Stockwork
  - Quartz stockwork
  - Limonite stockwork
  - Hematite stockwork
- Oxidation is confined to fractures and faults but can become disseminated in intensely fractured zones, large breccia zones and fault zones. Oxidation can occur at depths of 250 meters below the surface. Oxidation occurs as limonite and hematite.
- Structural controls include fault and fracture controlled mineralization in all zones identified on the Lincoln Hill property. In areas where conjugate faults oriented N40-70W and N50E result in large fractured zones conducive for hosting mineralization.
- Higher gold grades occur at the intersection of the steeply dipping northeast and northwest structures
- Higher gold grades can also occur at the intersection of the steep structures and a sub-horizontal silicified "cap"

The Main Zone is approximately 274 m (900 ft) along strike and approximately 61 m (200 ft) wide. It is characterized by high-angle N40W and N50E veinlets which constitutes 1-10 percent of the host rhyolite. The sub-horizontal silicification with gold extends for approximately 213 m (700 ft) towards the Shaft Zone. Low-grade gold and silver mineralization is associated with northwest to southwest trending quartz veinlets are closely associated with pervasive silicification. This blanket-like mineralized zone starts at the surface and has been drilled to a depth of 152 m (500 feet).

The Shaft Zone is approximately 244 m (800 ft) along strike and up to 18 m (60 ft) wide. It is characterized by high-angle N60E veins. The high-angle veins are associated with stockwork and breccias. The low grade gold and silver mineralization described in the Main Zone also occurs in the Shaft Zone. The Shaft Zone is open to the northeast and southwest.

The Lamprophyre Zone follows the N40W trending lamprophyre dike and is approximately 305 m (1000 ft) along strike and up to 15 m (50 ft) wide. Gold mineralization occurs in stockwork veins and veinlets on the selvages of the dike and grades averaging 7.5 opt gold have been reported from selective mining in the early 1900's. Later high-grade, coarse-gold is associated with a hematite-clay altered N45E trending tectonic fault-fracture system (manifested by breccias). These breccias intersect and slightly offset the lamprophyre dikes and associated gold-silver mineralization.

The Flat Zone is 180 m (500ft) along strike and 120m (393 ft) down dip between the Main and the Shaft zones. It is characterized by a silicified cap which is thicker at the margins, close to the adjacent Main and Shaft zones. This zone is newly defined and needs further study.

The Washington Zone, previously called the **Raven Zone**, consists of a NE fault zone, vertical to steep dipping to NW, filled by quartz vein. The hosted rock is a strong fractured rhyolite, intensely silicified and oxidized in the fault zone and in fractures. Quartz stockwork was also observed in surface at least 10m away of the fault. Drilling tested 400m in strike length but mineralization remain open. Soil anomalies and CSMAT indicates that mineralization can extend at least 400m to NE. 250m To SW, LRC-005 indicated presence of mineralization, narrow but high grade. Washington still remains mostly untested. Is approximately 122 m (400 ft) along strike and up to 9 m (30 ft) wide. The Raven Zone is open to the southwest.

Ouro Fino consists of a lamprophyre dyke oriented N40W dipping 60 degrees to NE. It has 0.6m in thickness cutting a weak altered rhyolite. No quartz stockwork is observed, only narrow quartz veins along of the contact rhyolite/lamprophyre dyke is present. Rhyolite is silicified and argillized but the intensity ranges from weak to moderate. Surface rock sampling shows some significant high grade in quartz veins but it was not confirmed by drilling.

Jefferson Zone outcrops in a small window located on the NW slope of Lincoln Hill. Surface mapping identified a N30-40W oriented lamprophyre dyke with a 40m strike length that had been historically mined. Mineralization occurs in rhyolite, as quartz stockwork veining, along the contact of the lamprophyre dyke and rhyolite. A 2010 ground magnetic survey indicated that the lamprophyre dike potentially has a 1.6 km strike length that continues under colluvium and the upper agillic altered rhyolite. The 2010 mag survey also indicated several parallel dykes. The Jefferson Zone was tested with drilling in 2010 and 2011 and confirmed the presence of three additional dykes as well as the identified mineralization identified through surface mapping. Through drilling, mineralization was extended 300 m from the outcropped area and 600 m to the SE. Drilling also identified mineralization along the contact between the upper rhyolite and the lower andesite contact and in areas where the NW dykes are intersected by NE faults.

Middle Dyke is poorly outcropping cutting the durmortierite alteration (exhalative origin of the upper volcanic unit outcropping at Lincoln Hill) and it is partially altered along of its NW end. Quartz stockwork was observed in some outcrops. It can be the SE extension of the main dyke offset by the Creek fault. It

has 1-2 m in thickness oriented N40W dipping steep to NE and extends for 400m. Drilling tested only the NW end and remains widely open to SE.

Exploration

Two zones, Roosevelt and B. Franklin, remain untested by drilling.

The Roosevelt zone is located SE of Lincoln Hill and consists of several small adits and shafts targeting quartz veins along the rhyolite and andesite contact and vertical veins in the rhyolite. The N-S mineralized zone is strongly silicified and is separated from Lincoln Hill by a major N-S fault.

The historic mines and prospects dotting the hillside are within a silicified rhyolite overlying intensely oxidized andesite. Grab rock-chip samples returned high-grade gold and silver values up to 34.79 g/t Au and 779 g/t Ag, 14 g/t Au and 183 g/t Ag, 97.92 g/t Au and 1527 g/t Ag and 97.5 g/t Au and 1303 g/t Ag along the rhyolite/andesite contact. A low-grade gold halo in the surrounding altered rhyolite returned gold values ranging from 0.11 g/t gold to 2.77g/t gold. The south end of the anomaly is covered by thick colluvium.

The Ben Franklin zone is located North of High Grade Canyon and South of the Ouro Fino zone and consists mainly of a moderate silicified rhyolite. Intense silicification was also observed but restricted in distribution. Stockwork is present but it is not wide spread. An altered lamprophyre dyke is present but no stockwork or quartz was observed in close association. Oxidation is moderate.

There are numerous prospect pits and underground workings at Lincoln Hill which occur in these different zones. This corresponds to the different mineralizing events and structures. Minor placer gold deposits have been worked below Lincoln Hill in High Grade Canyon.

Rock-chip sampling at the adjacent Independence Hill located 750 metres south of the Lincoln Hill resource area shows the Lincoln Hill geologic structures along with gold and silver mineralization continue. Samples collected from outcrop exposures at the Alexander Hamilton, Buck&Charlie, Looney, Hill Top, and Octopus historic mines confirm four separate high-grade corridors crossing Independence Hill which could extend gold and silver mineralization to the south.

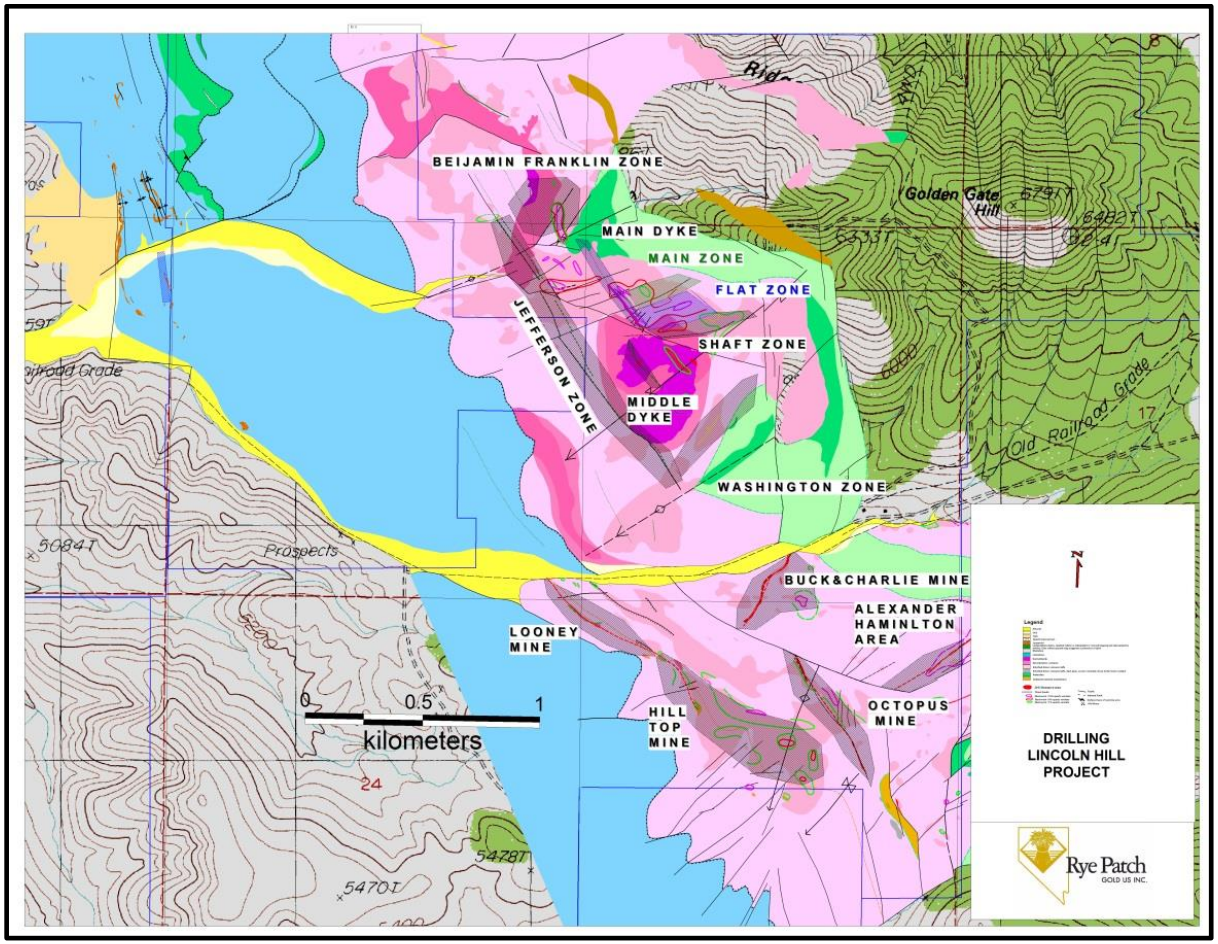
The Hill Top-Looney and Buck&Charlie mines represent two parallel trends extending south of the Lincoln Hill resource. The Hill Top and Looney mines are located on the same structural corridor with high-grade gold and silver sampled along 1.3 kilometres. The Hill Top mine consists of several historic workings following a quartz stockwork zone that extends for over 300 metres in a northwest-southeast orientation. The Hill Top mine returned significant lead and zinc values with lead ranging between 36 ppm to 51,100 ppm, and zinc ranging between 10 ppm to 4,694 ppm. The Buck&Charlie mine trend is located to the 750 metres east of the Hill Top-Looney trend. The structural zone has been mapped for over 400 metres.

The Octopus mine retuned several samples with significant gold and silver along 160 metre structural zone. Assay values reported include 1.62 g/t Au and 568.0 g/t Ag; 1.11 g/t Au and 77.6 g/t Ag; 0.05 g/t

Au and 497 g/t Ag; and 0.69g/t Au and 240.0 g/t Ag. The historic workings follow a northwest oriented breccia zone.

The Alexander Hamilton mine is located 800 metres east of Buck&Charlie mine and consists of a northeast oriented open-space breccia and quartz stockwork zone oriented to the northeast.

Figure 7.4 Geologic Map of Lincoln Hill Showing the Areas of Mineralization



Map From Rye Patch US

8 DEPOSIT TYPE

Lincoln Hill exhibits many characteristics of other precious metal vein systems in the Great Basin, such as Tonopah, Goldfield and Virginia City, but also has characteristics in contrast to these bonanza systems (Vikre, 1981). The similarities are 1) host extrusive rocks, 2) Bonanza veins and 3) some components of the wall-rock alteration and vein mineralogy. The main differences are the age of the host rocks and the timing of mineralization related to the host rock formation. Lincoln Hill is a high-grade, gold-silver-quartz-pyrite-tourmaline-sericite stockwork vein system overprinting a large low to moderate grade disseminated replacement precious metal mineralizing system. The host rocks are the Permo-Triassic island arc volcanic rocks of the Koipato Group. Gold mineralization has been identified over an area 1.6 by 2.4 km (1.5 by 1 mi) and to a depth of >305 m (1000 ft). Rye Patch US believes that the folding faulting, alteration and mineralization are related to several porphyry-style intrusions emplaced in this portion of Nevada.

Lincoln Hill lies within the newly named Oreana Trend (Pinto da Silva and Howald, 2009). This mineralized corridor extends from the Willard/Colado (Wilco) area to the Spring Valley deposit. It is characterized by the alignment of recent and historic gold and silver deposits and occurrences.

The main exploration target has been the gold and silver mineralization associated with the densely silicified quartz+tourmaline+dumortierite+sercicite zone that caps Lincoln Hill. A high-grade, coarse-gold-bearing quartz-tourmaline-sericite-clay altered stockwork-vein system is associated with N30º to 60ºW striking, altered lamprophyre dikes. The north-south and northwest structural zones contain diabase intrusions and lamprophye dikes that suggest deep crustal structures. These deep seated structural zones were important for the emplacement of the intrusive and as possible pathways for gold and silver mineralization.

Most authors have hypothesized multiple mineralizing events at Lincoln Hill (Schrader, 1913; Knopf, 1924; Vikre, 1981; Callicrate and Griffin, 2007). Pinto da Silva and Howald (2009) confirm that Rye Patch also believes there were several mineralizing events that have deposited and remobilized the precious metals. The separation of these events at Lincoln Hill is critical in defining the areas prospective for concentration of gold and silver.

9 EXPLORATION

Since acquiring Lincoln Hill in 2007, Rye Patch US has thoroughly evaluated the historic data, completed a geologic map and sampled outcrop and dumps. Based on this work they drilled 98 RC and 9 core holes in 4 drill campaigns (2008 – 2011). Prior to Rye Patch US's involvement at Lincoln Hill several companies have conducted exploration activities at Lincoln Hill, which are described in Section 6. Coeur and Newmont have drilled 8 RC holes, respectively.

Through geologic mapping, surface sampling (rock and soil), geophysics and systematic evaluation of the drill results has led Rye Patch US to define at least 10 separate areas of gold mineralization (Figure 7.4).

The following brief description of exploration activities will focus on the geologic interpretation and geochemistry that was used to target the drilling program and the next phase of work at Lincoln Hill.

9.1 GEOLOGY

The detailed geologic mapping completed by Rye Patch US (Pinto da Silva, 2012) defined the different mineralized zones described above in Section 7.3. Variations in structural setting and hydrothermal alteration define the following mineralized zones:

- Main Zone: N50E, steeply dipping; sub-horizontal silicification,
- Shaft Zone: N60E, sub-horizontal silicification near surface and breccias following x-cutting structures
- Lamprophyre Zone: N40W, quartz stockwork along dike margin with breccias cutting and offsetting the dike.
- Flat Zone: It occurs between the Main and Shaft zones.
- Raven Zone: N50E
- Ouro Fino: N40W, .5m wide lamprophyre dike with mineralization along dike margins
- Washington Zone: N50E, one meter wide fault zone with mineralization including adjacent fractured zones.
- Jefferson Zone: N30W, 1.5km long lamprophyre dike/fault zone offset by a series of N50E normal faults. Mineralization occurs along dike margins and increases in thickness and grade where the structures intersect.
- Middle Dyke: N35W, .5 to 2 m wide lamprophyre dike with a strike length of 400m. Mineralization occurs along the margins of the dike.
- Exploration (Roosevelt and B. Franklin):
  - Roosevelt: N40E quartz vein breccia along Rochester rhyolite and andesite contact.
  - Ben Franklin: N40W and N50E quartz stockwork zones and quartz veinlets.

All of the zones have strong silicification (dense replacement and quartz stockwork veins/veinlets), a halo of strong argillization around and beneath the silicification and pyrite destruction. The highest grade gold generally occurs where steeply dipping, northwest and northeast structures intersect. Additionally, the intersection of high angle faults with the sub-horizontal silicified body has concentrated gold.

9.2 GEOCHEMISTRY

The surface sampling along with the geologic mapping completed by Rye Patch US, confirmed that gold and silver mineralization occurs in several zones and in at least two mineralizing events. Lincoln Hill has high-grade gold mineralization and Rye Patch US has returned up to 26 g/t Au from a rock chip sample in a mine stope. Low-grade gold mineralization occurs over a widespread area. The Rochester mining district has produced over 128 million ounces of silver and there is also a wide halo of elevated silver.

Rye Patch US contracted Vic Chevillon, Chevillon Exploration Consulting, to study the trace drill hole trace element data (Chevillon, 2009). He modeled the lithologic contacts and all of the ICP geochemical data using GoCAD (Figure 9.1), and distinguished the following elemental patterns:

- Central MO, As, Sb, Pb
- Stratabound (across the domains) Ag, Au, La, Ca
- Stratabound W; V and Na
- East; K, Be, B?, Ga,
- Asymmetric to E; Sc, Zn, Mg, Al, Cr, P, W?, Ca
- Fe, S, Ni, Hg? Clusters across domains which may coincide w/higher gold grades
- Au shows a similar coplanar configuration to the only lithologic contact modeled.

Only one lithologic contact could be modeled, 225 degrees, -30 degrees, and gold shows a similar coplanar configuration (Figure 9.1). This could indicate a stratabound nature of the gold mineralization at Lincoln Hill. Additional work is required to validate this hypothesis.

The historic and Rye Patch Gold US Inc. rock chip sampling shows the relation between the gold and silver mineralization between the different zones (Figure 9.2 and Figure 9.3).

A soil sampling program was conducted SW of the Washington Zone towards the hinge zone of an anticline located at the SW corner of the property. 102 samples were collected and the average grade of the samples is 9 ppb Au and 0.6 g/t Ag. The highest value is 35 ppb Au and 2.8 g/t Ag. The soil anomaly decreases towards the SW, suggesting a plunge in the mineralization parallel to the anticline. Towards the NE, the soil anomaly extends for 700m and the highest value sampled has a grade of 160g/t Au and 8.2 g/t silver.

In 2011, 1,564 samples were collected in a large soil sampling program surrounding Lincoln Hill (Figure 9.4 and Figure 9.5). Soil sampling also identified two new targets named Roosevelt and B. Franklin. The Roosevelt target is located SE of Lincoln Hill and has a 300m strike length. Four of the samples taken at this target have values greater than 100 ppb Au, including one sample of 123 ppb Au and 100 ppm Ag. Twenty four rock chip samples were collected to follow up on the highly anomalous soil samples and 10 samples had values greater than 0.5 g/t Au. The highest grade sample was 97.5 g/t Au and 1303 g/t Ag.

The second target, North of Lincoln Hill, was named B.Franklin. This target has a strike length of 300m defined by soil samples values ranging in values from 25 to 50 ppb Au. The highest soil sample taken has

a value of 53 ppb Au and 53 ppm Ag. Six rock chip samples were collected to follow up on the highly anomalous soil samples. The highest grade rock chip sample taken at this target has a value of 0.119g/t Au and 7.6 g/t Ag.

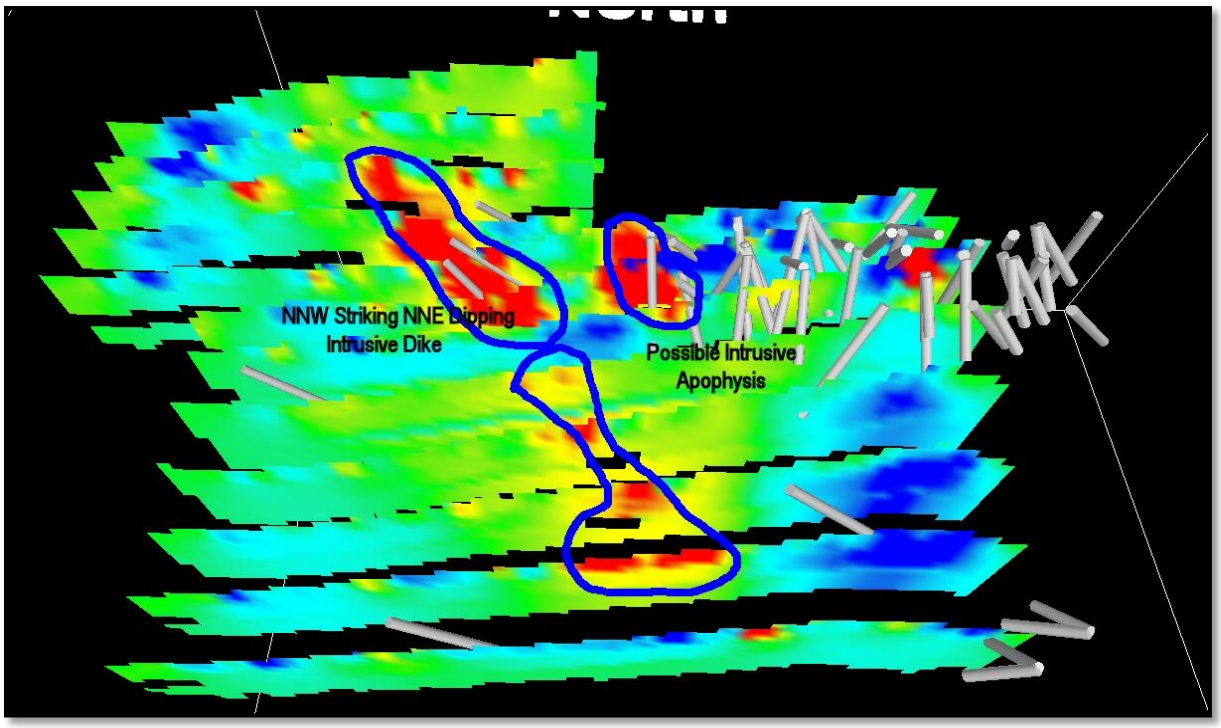
9.3 GEOPHYSICS

9.3.1 2010 MAG SURVEY

Ground Magnetic survey collected points at an average interval of three meters and heights of about three meters for a total line distance of 150 kilometers. A total of 60 lines at an interval of 50 meters and lengths of 2.5 meters were surveyed. MaGee Geophysical Services processed and interpretations were made by Terry White of Rockgeophysics (Figure 9.6). In the figure, magnetic highs are shown with warm colors and magnetic lows are shown with cool colors. High magnetic anomalies are interpreted as zones with intrusive lamprophyre dikes.

Figure 9.6 Ground Magnetic Survey Results



9.3.2 2011 CSAMT SURVEY

Zonge Geosciences, Inc. (Zonge) performed a controlled-source, auto-frequency, magnetotelluric (CSAMT) survey on the Lincoln Hill Project, located in Pershing County, Nevada for Rye Patch US. This survey was conducted during the period of 16 August to 2 September 2011. The survey area is located in Township 28 North and Range 22-24 East, and lies within the Rochester, Nevada 7.5-minute topographic map. CSAMT data were acquired on fifteen lines for a total of 33 line-kilometers of data coverage. Line locations are shown in Figure 9.7.

Data were acquired along fifteen lines oriented east/west. Zonge personnel established survey control points for this project using Trimble PRO-XRS GPS receivers. The GPS data were differentially corrected in real-time using WAAS corrections. This system provides sub-meter accuracy under standard operating conditions. Line control in the field utilized UTM Zone 11N NAD83 (CONUS) datum.

Results from the two-dimensional inversions of the data are presented as color-contoured pseudosections. In these plots (Figure 9.8– Figure 9.11) low resistivities are shown with warm colors (red, violet) and higher resistivities are shown in cool colors (blue, white). It is important to note that the smooth-model inversion shows gradational changes in resistivity, rather than abrupt changes, irrespective of the actual geologic structure.

CSAMT Data was analyzed and interpreted by Terry White of Rockgeophysics (Figure 9.12).

10 DRILLING

Rye Patch US has drilled 98 RC and 9 core holes for a total of 16,941.76 meters at Lincoln Hill. Prior to Rye Patch US, Coeur Exploration drilled 8 RC holes and Newmont drilled 8 RC holes for a total of 2,637 meters. The location of the holes is shown in Figure 10.1 and Figure 10.2 and Figure 10.3 displays Lincoln Hill drill holes in an isometric view. All drilling was completed at Lincoln Hill in nine defined target zones: Lincoln Hill (includes; Lamprophyre, Shaft, Flat, Main) and satellites targets: Ouro Fino, Washington, Jefferson, and Middle Dyke. Drill hole selection was based on the geologic and structural interpretation of the previous drilling results in conjunction with the geologic mapping completed in 2009 and magnetic anomalies interpretation. The majority of the holes were drilled at an angel to intersect potentially high-grade structural zones. Drill hole collar data and results from the historic drilling and drilling completed by Rye Patch US from 2008 to 2011 are listed in Table 10.1– Table 10.15.

The Rye Patch US drilling started in 2008 and was completed in 2011. During 2008, 23 RC holes were drilled in the central portion of the property, primarily in the Main, Lamprophyre, Flat and Shaft zones. The exploration program cut multi-ounce gold and silver intersections in drill hole LR-013 including 25 feet grading 2.2 ounces/ton gold from 90 to 115 feet down hole. In addition, there were numerous significant gold intervals encountered in the program. A total of 2,550 meters in 18 reverse circulation drill holes were completed. The follow-up reverse circulation drilling program at Lincoln Hill shows the at-surface stockwork gold and silver zone is still open along strike and at depth. This stockwork blanket zone is “rooted” in a breccia pipe which may host higher grade gold and silver values along its margin.

The drill hole analytical results indicate the stockwork mineralization hosts high-grade structurally controlled gold and silver (21.3 meters grading 27.2 g/t Au and 34 g/t Ag including 7.6 meters grading 75.4 g/t Au and 82 g/t Ag) surrounded by a near surface, stockwork gold and silver zone. To ensure gold assays captured the higher grade portion of the gold system, selected intervals from drill holes LR-019, LR-021 and LR-023 were re-run using metallic-screen, fire-assay analysis. The results of this study show gravity separation (coarse gold) is a potential assay issue that should be addressed in future drilling programs (Table 10.16). Additional study is warranted to fully ensure the assay results to date capture the coarse gold and produce representative assay values.

Another 20 RC holes and 4 core holes were drilled in 2009. The drill program included a few holes within the main zones drilled in 2008 and 13 RC holes in targets outside of the main body of alteration and mineralization. The initial reverse circulation drilling results expanded the at-surface stockwork alteration zone 500 meters southward into the Raven target area. Drill holes LR-026 and LR-027 show the halo mineralization is concentrated at the intersection of northwest oriented lamprophyre dike and northeast trending fractured zone.

Drill holes LR-028 to LR-030 were drilled within the main Lincoln Hill zone and expanded the zone to the north and northwest. The mineralized zones are associated with an at-surface stockwork gold and silver zone and intersected zones of high grade. LR-030 shows additional high-grade gold and silver zones exist within the broader halo mineralization.

Using a gold equivalent grade of 0.34 g/t AuEq, the halo mineralization ranges between 10 and 49 meters in thickness and has gold and gold equivalent grades ranging between 0.5 g/t AuEq to 1.65 g/t AuEq in these five drill holes. The stockwork zone has been observed in surface outcrop and in drill holes over an area of 2,000 by 300 meters.

During 2010, 15 RC drill holes were drilled in three different zones (Washington, Lincoln Hill and Middle Dyke) for a total of 2,403.35 meters. Drill holes LR-046 and LR-052 were drilled in the Washington zone and intercepted several low grade intervals associated with a prominent fault zone and stockwork veining. These holes also extended mineralization 100 meters SW of the old Raven Mine. Drilling at Lincoln Hill zone expanded the know mineralization to the South and remains open. Drill hole LR-051 was the first hole to test the SE extension of the Jefferson zone and intercepted a broad zone of low grade mineralization (19 meters of 0.17 g/t Au, 15 g/t Ag). Mineralized quartz veins, parallel to lamprophyre dykes, that had been previously mined on the surface were drilled to test the vertical down dip extension. Drilling at the Middle Dyke zone targeted previously intercepted high grade mineralized stockwork zones near several lamprophyre dykes. Drill hole LR-056 intercepted a high grade silver zone (3 meters of 0.72 g/t Au and 164 g/t Ag) along the margins of a lamprophyre dyke.

The 2011 drilling program consisted of 40 RC holes and 5 core holes for a combined 8,257.55 meters of drilling. Drilling efforts targeted four different zones (Washington, Lincoln Hill, Jefferson and a geophysical magnetic anomaly). Washington zone mineralization was extended 300 meters to the SW when drill hole LRC-005 intercepted a narrow high grade zone (1.1 meters of 5.9 g/t Au and 64.9 g/t Ag).

Jefferson zone mineralization was again expanded through drilling efforts. The mineralized zone grew 40 meters wider and 150 meters to the North West. Drill hole LR-061 intercepted a 3 meter mineralized interval with 0.25 g/t Au and 509.5 g/t Ag.

Two drill programs were implemented to test the Jefferson zone mineralization. The first program included drilling nine holes in the northern part of the Jefferson zone. Mineralization was intercepted during the program extending the Jefferson zone 150 meters to the North West and expanding the zone by 40 meters to the South West. The second program was designed to test the Jefferson Zone mineralization at several different elevations in the Rochester Rhyolite. Drilling results indicate that mineralization is restricted to the lower part of the rhyolite and the underlying andesite. Also, structural intersections within the rhyolite appear to contain wide mineralized zones with high grade. Drill hole LR-067 crossed a structural intersection and intercepted 47.2 meters of 0.23 g/t Au and 27.8 g/t Ag included; 1.5 meters of 0.87 g/t Au,121 g/t Ag).

Drilling in the Lincoln Hill zone extended mineralization the North East (LR-079) and South West (LRC-007) and confirmed continuity of mineralization at depth. Drill hole LR-075 intercepted 1.5 meters of 3.1 g/t Au and 27.1 g/t Ag. Drilling efforts also included infill drilling (LR-090) to upgrade the known resource for the 2012 model. Drill hole LR-090 intercepted two 1.5-meter zones with 0.76 g/t Au and 308 g/t Ag and .83 g/t Au and 134 g/t Ag.

Core and RC drilling show the main Lincoln Hill target contains significant high-grade gold and silver along northeast trending structures within the broader quartz stockwork halo zone. The core shows the broader stockwork mineralization has a high-angle as well as a horizontal or bedding controlled component. LRC-002 intersected veins and veinlets and shows visible gold in several veins over the 15.8 meter zone. The vein arrays are hosted within a thicker zone of altered, silicified rhyolite volcanic rocks. The intersection of the favorable units within altered rhyolite and northeast structures appear to control high-grade gold and silver distribution within the stockwork gold zone. LRC-003 shows the disseminated nature of the stockwork zone with 33.1 meters grading 1.10 g/t gold.

11 SAMPLE PREPARATION, ANALYSES AND SECURITY

11.1 SUMMARY

Rye Patch US has collected and submitted drilling (RC and core) and rock samples for analyses. All samples were submitted to one of three laboratories; ALS Chemex (Reno, NV), Alaska Assay Labs (Fairbanks, AK) (AAL-AK) or American Assay Labs (Sparks, NV) (AAL-NV). Drill hole samples from previous companies were submitted to several reputable laboratories and it is expected that they utilized industry accepted standards for both preparation and analyses.

All of the laboratories that Rye Patch uses are ISO certified and reputable.

It is SWEC's opinion that Rye Patch uses best industry practices for sample collection, sample preparation, security and analysis.

11.2 SAMPLING METHOD AND APPROACH

11.2.1 ROCK CHIP SAMPLING

Rye Patch geologists have taken 151 rock chip samples. They collected samples from mine dumps, outcrop, and underground workings. Samples were collected primarily to determine the areas with the highest grade gold mineralization and confirm the historic rock sampling. At each sample site the following were recorded; location, rock type, formation, degree and type of alteration, mineralization and sample type. This work was supervised by a Qualified Person and the author believes that the sampling was adequate for the geology, mineralization and level of exploration conducted at Lincoln Hill.

Rock sampling has been completed by previous companies and is assumed that the sampling was conducted according to industry standards, although the author cannot verify or certify the results. These results are used in this report for descriptive purposes and they are not being used in a resource calculation. They are simply used to indicate the extent of surface mineralization and as one of the tools used to target the drill holes that Rye Patch US completed during 2008, 2009, 2010 and 2011.

Rock chip samples are shown in Figure 9.2 and Figure 9.3 and are color coded by their respected Au and Ag grades.

11.2.2 DRILL SAMPLING

Rye Patch US used industry standard practices during their drilling programs. Both RC and core were collected (43 RC holes and 4 core holes). Drill holes were oriented to cross the mineralized zones based on surface and underground geologic mapping and the results of historic drilling.

The RC samples were collected for each 1.5 m (5 ft) interval over the full length of the drill holes. The first 1.5-6.1 m (5-20 ft) of each drill hole was drilled dry and then casing set. The dry samples were split using a Gilson dry splitter. After casing was set, water was injected and the remainder of the drill hole was drilled using wet methods. A rotating wet splitter was used and the splitter was adjusted by the

geologist or sampler as needed to control the amount of sample collected in the bag (bucket). When possible the sample bag was attached to the sample exit and a 4.5-9 kg (10-20 lb) sample was taken. The bag was also placed in a 1.1 liter (5 gallon) bucket, when needed and the sample was collected. The sampling methods utilized are industry standard. Rye Patch US utilized blanks, reference standards and duplicate samples to monitor quality control of their drill samples.

The samples collected by Rye Patch US were sufficient to accurately represent the mineralized zones of Lincoln Hill. The 4.5-9 kg samples are sufficient to yield good quality assay values. With samples being placed in buckets, fine particles of gold were captured which reduced sample bias. There were no issues with sample recovery in the Rye Patch US drill sampling program.

Coeur and Newmont drilled a total of 16 RC holes on the property. Their sampling methods and approach are not known. They probably utilized procedures that were up to industry standards at that time. No rigorous review of the historic drill results was completed for this technical report, and therefore the drill process, sampling and analytical methods are not known.

There were 4 core holes drilled by Rye Patch US at Lincoln Hill and all the drilling was HQ or NQ. Rye Patch US sampled on 5 foot intervals, adjusting the sample widths when geology or mineralization changes were noted. All samples were >=0.3 m (1 ft). The core was taken from the site daily to the core logging facility in Lovelock or in Reno, Nevada. After logging the core was taken to American Assay Laboratories in Reno and their laboratory technicians split the core according to the intervals specified by Rye Patch US geologist Ronaldo Pinto da Silva.

All drill holes were surveyed for deviation and most did not deviate more than a few degrees. Recovery in both methods was good, except in areas of strong faulting.

The relevant Rye Patch US drill hole sample results are shown in Table 10.3, Table 10.5, Table 10.7, Table 10.9, Table 10.11, Table 10.13 and Table 10.15.

11.3 SAMPLE PREPARATION

Sample preparation is conducted at the ISO certified laboratories. No officers, directors, or associates of the issuer are involved in sample preparation.

11.3.1 SAMPLE COLLECTION

Assay certificates exist for virtually all of the drill holes at Lincoln Hill. The sample collection process for the historic drill holes is not documented, although it is assumed to be equal to industry accepted standards at the time. Likely the dry samples were collected using a riffle splitter and the wet samples using a rotating wet splitter.

Present sample collection procedures include dry sampling at the top of the hole until casing is set and then wet sampling for the remainder. The specifics of the sample procedure are described in Section 12.1.

11.3.2 SAMPLE PREPARATION AND ANALYSIS

The sample preparation procedure is:

- Samples are weighed, dried and reweighed
- A 1 kg split is pulverized the >85% passing 75 microns
- Au-Ag assay followed by gravimetric AA finish
- Multi-element ICP by four acid near total digestion
- Hg by aqua regia digestion AA

11.4 SAMPLE SECURITY

11.4.1 REVERSE CIRCULATION AND CORE SAMPLE SECURITY

Reverse circulation and core samples were kept on-site until transport to the laboratory. ALS Chemex and American Assay pick up the samples at the site. Alaska Laboratory has a preparation facility in Lovelock, NV and the Rye Patch US geologist delivered the sample to their laboratory.

Samples are delivered in numbered bags with a transmittal sheet. Blanks, reference samples and duplicates are submitted with each sample batch.

11.4.2 ANALYTICAL RESULTS

Following analysis, analytical results are posted to a digital database which is available to Rye Patch US through secure permission privileges. The completed digital file is emailed and a hard copy mailed to Rye Patch US.

The data is downloaded to an Excel file and cross-referenced with the drill hole information (hole number, footage interval) and the blanks, reference samples and duplicates are checked.

12 DATA VERIFICATION

12.1 QA/QC, CHECK SAMPLES AND CHECK ASSAYS

12.1.1 REVIEW

As part of their company QA/QC program, Rye Patch US hired a third party consultant, Shea Clark Smith, Minerals Exploration and Environmental Geochemistry (MEG), to conduct and oversee the QA/QC program for the Lincoln Hill project. The following is based on his reports to Rye Patch.

12.1.2 RYE PATCH GOLD US INC'S 2008 DRILL HOLE QA/QC PROGRAM

Drill samples for the 2008 drill program were submitted to ALS Chemex with reference standards and blanks to determine data accuracy and precision. Additionally internal laboratory standards and prep blanks comprised approximately 8 percent of the total drill samples reported. The following summarizes the quality assurance / quality control (QA/QC) data for Drill Holes LR001 through LR018, but not including LR007, LR013, LR016, and LR017. 81 standards and 12 prep blanks were submitted, along with 1180 drill core samples, for a total of 1273 analyses. QAQC samples are 7.9% of the total number of assays reported (Smith, 2008).

Select drill samples from Lincoln Hill were submitted to Florin Analytical Services (Reno, NV) in 2010 with standards, blanks, and duplicates to determine data accuracy and precision while checking previous assays from Alaska Assay Labs (Fairbanks, AK) (AAL-AK), American Assay Labs (Sparks, NV) (AAL-NV), and ALS Chemex (Reno, NV). The samples were from selected intervals from drill holes LR-004, LR-008, LR-009, LR-010, LR-011, LR-013, LR-015, LR-026, LR-027, LR-028, LR-030, LR-031, LR-032, LR-033, LR-034, LR-035, LR-045, and LRC-001 that were suspect from earlier analyses due to a high incidence of QAQC failure.

12.1.2.1 2008 GOLD RESULTS

In the 2008 sample submissions, 17% of the samples submitted had >2 standard deviation errors in the Au standards, including drill holes LR009 and LR015. These errors are spread evenly through the data and other QA/QC data indicate general assay quality. In one ALS Chemex job (LR002), data for samples 385-390 and 385A-390A appear to have been switched, as indicated by the fingerprint of trace concentrations for the standard (385A-390A) (Smith, 2010a).

Results from the 2010 submittal to Florin Analytical Services indicate that Florin reported lower gold concentrations than expected. Based on the entire body of data from the QA/QC program, gold and silver data as reported by Florin are reliable despite a high QAQC failure rate (Smith, 2010b). At lower concentration levels, Florin generally reports slightly higher concentration of gold and silver than AAL-NV, ALS Chemex and AAL-AK (see Figures 14.1 and 14.2). The objective was to determine the reproducibility of the original data from ALS Chemex, AAL-NV, and AAL-AK. Since differences are small, these data are considered to be good representations of the true gold and silver concentrations of the samples.

12.1.3 2008 SILVER RESULTS

In general, Florin reported lower gold concentrations than expected, yet higher silver concentrations (Smith, 2010b). This also includes 3 out of 3 certified blind standards that report silver concentrations either above or below the mean by greater than 2 standard deviations (95% confidence interval), and another 19 values that qualitatively fall significantly higher or lower than the expected mean value. As mentioned above, his objective was to determine the reproducibility of the original data from ALS Chemex, AAL-NV, and AAL-AK. Since differences are small, these data are considered to be good representations of the true gold and silver concentrations of the samples.

12.1.4 RYE PATCH GOLD US INC'S 2009 DRILL HOLE QA/QC PROGRAM

Drill samples from the Lincoln Hill Project were submitted to AAL-AK, and AAL-NV with standards, blanks, and duplicates to determine data accuracy and precision. Blind samples comprised approximately 9 percent of the total number of drill samples reported. Internal laboratory standards and duplicates comprised approximately 10 percent of the total drill samples reported. Samples for drill holes LR-026 to LR-030 were submitted to AAL-AK only and the samples for the remaining drill holes were submitted to both AAL-AK and AAL-NV.

Following the submittal of the first samples to AAL-AK only, Mr. Smith found the analytical results to be generally unacceptable based on the standards, blanks and duplicate results. Mr. Smith thus recommended that pulps or rejects be submitted to another laboratory and that all future analytical work be checked by another laboratory (Smith, 2009a).

The remainder of the drill holes was submitted to AAL-AK and AAL-NV. Mr. Smith found that the samples submitted to AAL-AK continued to have a high failure rate and that AAL-NV sample results were reliable based on the reference samples submitted (Smith, 2009b).

Select drill samples from Lincoln Hill were submitted to Florin Analytical Services (Reno, NV) in 2010 with standards, blanks, and duplicates to determine data accuracy and precision while checking previous assays from Alaska Assay Labs (Fairbanks, AK), American Assay Labs (Sparks, NV), and ALS Chemex (Reno, NV). The samples were from selected intervals from drill holes LR-004, LR-008, LR-009, LR-010, LR-011, LR-013, LR-015, LR-026, LR-027, LR-028, LR-030, LR-031, LR-032, LR-033, LR-034, LR-035, LR-045, and LRC-001 that were suspect from earlier analyses due to a high incidence of QAQC failure.

12.1.4.1 2009 GOLD RESULTS

In the 2009 sample submissions to AAL-AK, more than 30% of the QA/QC samples submitted had >2 standard deviation errors in the Au standards, and the failure rate erred below the accepted confidence ranges more than 90% of the time (Smith, 2009a). Selected drill samples were resubmitted to Florin Laboratories in 2010 with blind standards to determine the reproducibility of the original data. Results from the 2010 submittal to Florin Analytical Services indicate that Florin reported lower gold concentrations than expected. Based on the entire body of data from the QA/QC program, gold and silver data as reported by Florin are reliable despite a high QA/QC failure rate(Figure 12.1). The objective

was to determine the reproducibility of the original data from ALS Chemex, American Assay, and Alaska Assay. Since differences are small, these data are considered to be good representations of the true gold and silver concentrations of the samples (Smith, 2010b).

12.1.4.2 2009 SILVER RESULTS

AAL-AK used silver standards infrequently and therefore there is no measure of silver reliability in their original data. The Florin data, which compared well to the AAL-AK, AAL-NV and ALS Chemex data indicates that the Florin silver results are slightly higher than the other laboratories, but the results are good (Figure 12.2).

Figure 12.1 QA/QC Comparison of Florin Gold Data With The Original AAL-AK, AAL-NV and ALS Chemex Analytical Data. Graph From Smith, 2010b

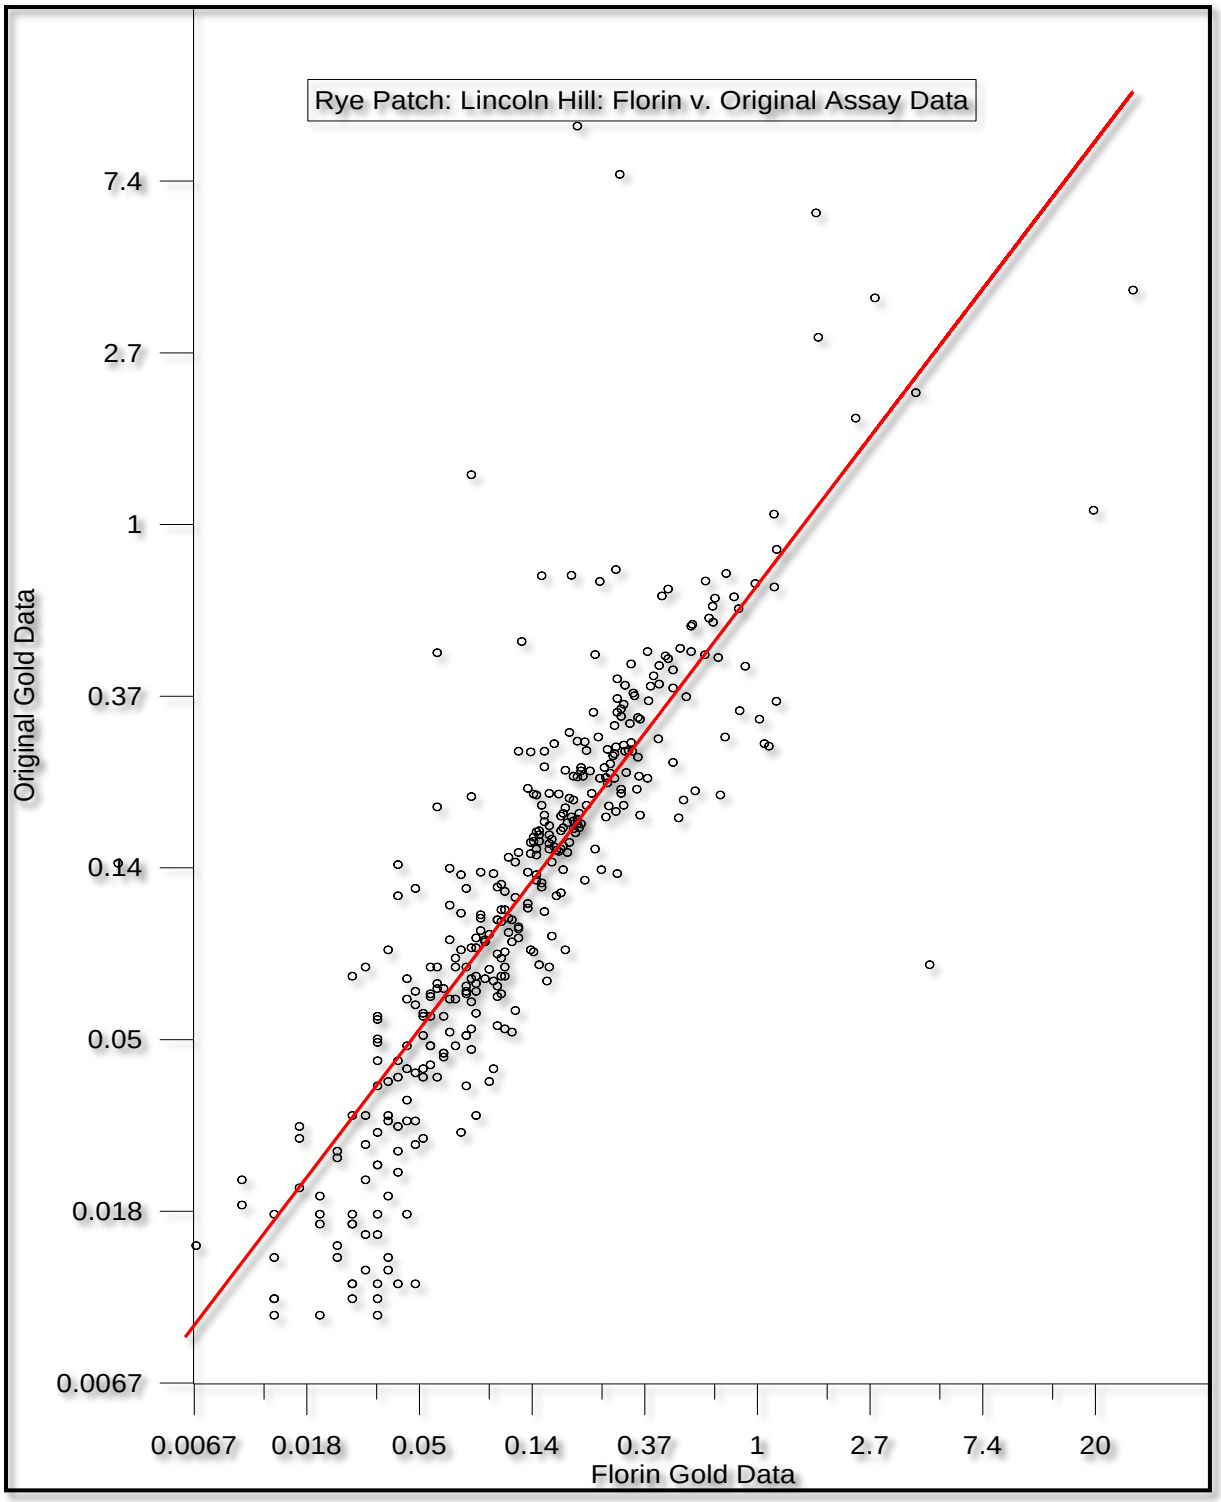

Figure 12.2 QA/QC Comparison of Florin Silver Data to AAL-AK, ALL-NV and ALS Chemex Analytical Results. Graph From Smith, 2010b

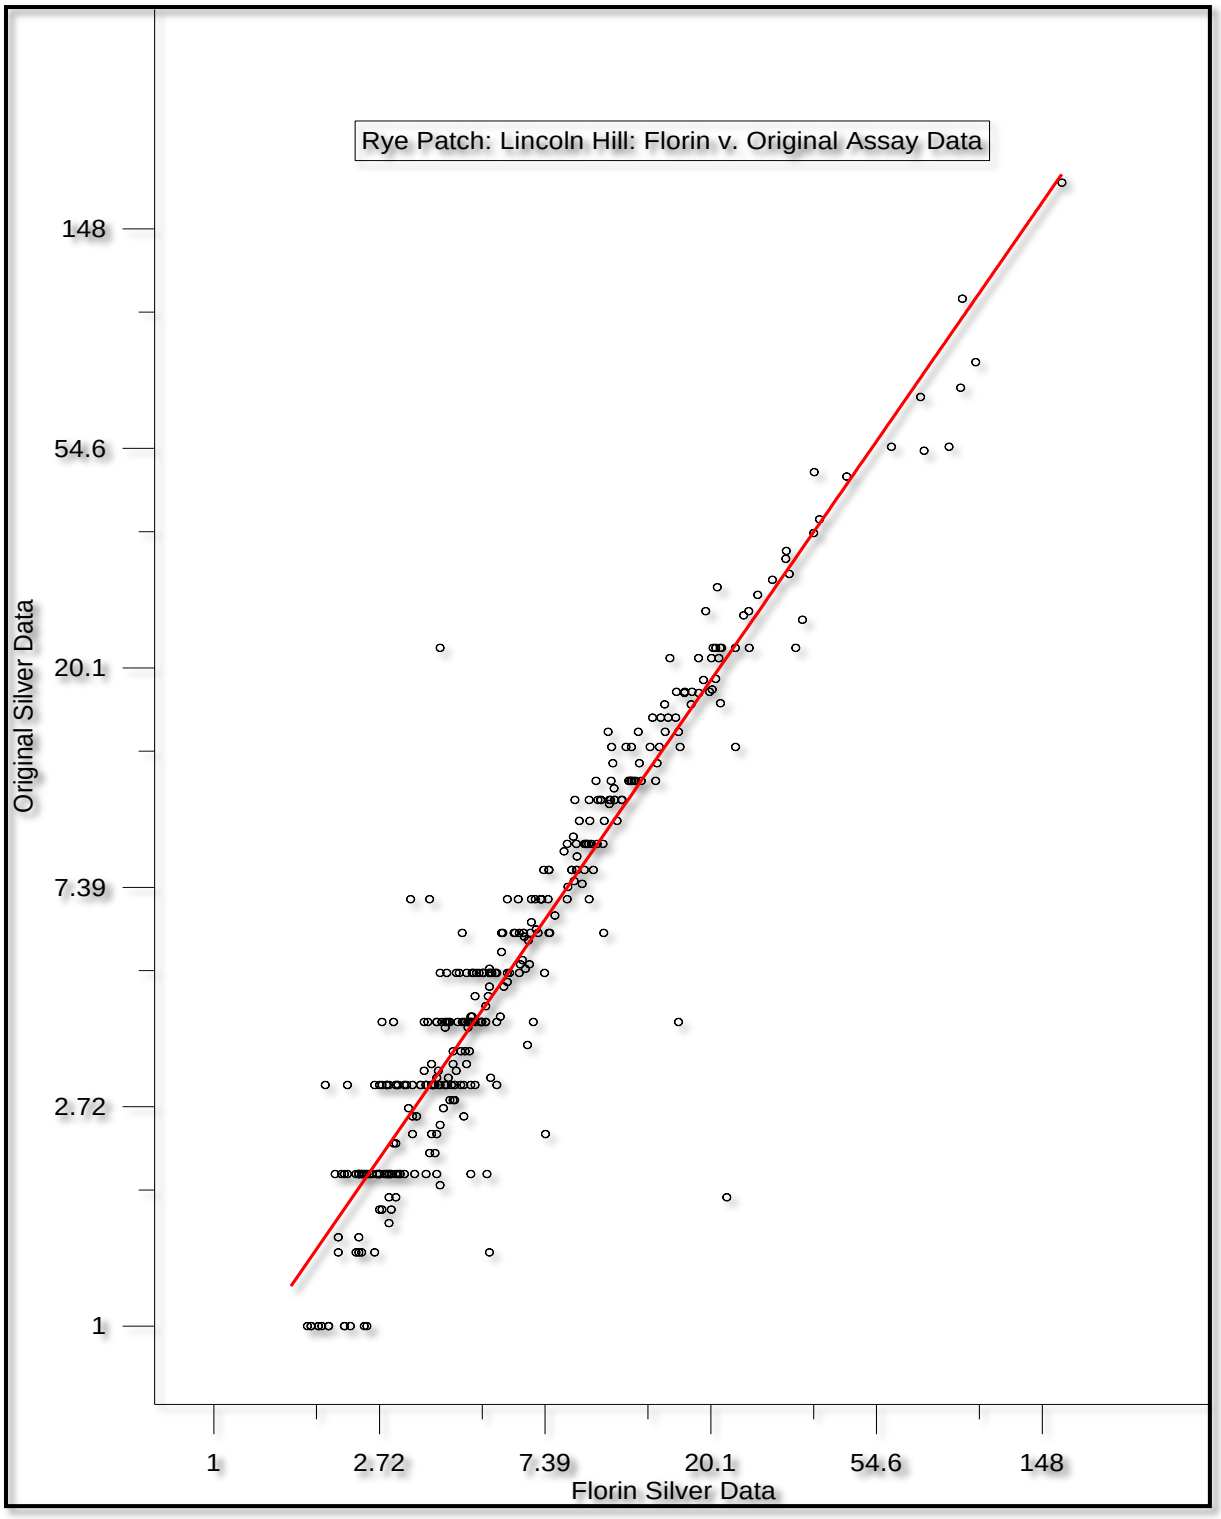

12.1.5 RYE PATCH GOLD US INC'S 2011 DRILL HOLE QA/QC PROGRAM

Drill samples from the 2011 drill program were submitted to American Assay Laboratories (AAL, Sparks, NV) with reference standards, blanks, and duplicates to determine accuracy and precision. The following summarizes the quality assurance / quality control (QA/QC) data for Drill Holes LR-061 through LR-100. 442 standards and 73 blanks were submitted, along with 4179 drill samples. QA/QC samples are 12.3% of the total number of drill assays reported (Smith, 2012).

12.1.5.1 2011 GOLD AND SILVER RESULTS

In the 2011 sample submissions, 3.3% of the standards and blanks reported above or below the mean by >2 standard deviations. Two of these failures are due to analysis of a sample instead of a designated standard, which might be geologist error or laboratory error. So actually, 2.9% of the standards and blanks failed analytically. Eleven gold analyses were reported below the 95% Confidence level, while four reported above the 95% Confidence interval. Gold in concentrations of about .2 ppm failed most frequently. Silver reported above the 95% Confidence interval four times. One value was for a blank sample that was misidentified as a sample, and three were above characterization values that were not certified. In conclusion, an overall failure rate of 2.9% is exceptional, indicating that the sample assays are reliable for gold estimation (Smith, 2012).

12.2 MMC DATA VERIFICATION

MMC believes the exploration programs as described in this report were conducted by commonly accepted industry standards. Current database compilation, completed by Rye Patch US, has been professionally managed and the programs conducted to high standards. MMC relied upon the Rye Patch US databases to gauge the nature of the mineralization at Lincoln Hill. MMC had full access to all of the Lincoln Hill assay certificates and no limitations were placed upon the author's ability to verify the accuracy of the Lincoln Hill data.

During the July 20th, 2012 site visit, Scott E Wilson collected three core samples without Rye Patch interference. The samples were prepared and analyzed at ALS Chemex Laboratories in Reno, NV. The verification samples confirm that mineralization is present at the Lincoln Hill ore deposit (Table 12.1).

Table 12.1 MMC Verification Samples

Sample	Zone	From (m)	To (m)	Database Sample		Verification Sample	
				Au ppm	Ag ppm	Au ppm	Ag ppm
LRC-001	Main Zone	10.36	11.89	2.79	8.6	0.28	6
LRC-002	Main Zone	56.39	57.30	1.21	23.6	1.24	51
LRC-005	Washington Zone	150.08	151.21	5.9	64.9	1.82	23

13 MINERAL PROCESSING AND METALLURGY

Rye Patch Gold contracted Kappes, Cassidy and Associates (KCA) of Reno, Nevada to conduct bottle roll metallurgical testing. Twelve separate composites were identified by rock type, silicification, oxidation state, and gold grade. Composites were composed from drillhole samples from across the ore deposit (Table 13.1). The twelve composites were selected based on attributes of rock type, alteration, and oxidation state (Table 13.2) within three gold grade ranges (Table 13.3) for the Lincoln Hill deposit.

Oxide Results: The results from 10 P80 mesh (1.7 mm) on oxide material averaged recoveries of 76% recovery for gold and 79% for silver while P80 150 mesh on oxide material averaged recoveries of 86% for gold and 87% for silver, and P80 200 mesh recoveries on oxide material averaged recoveries of 85% for gold and 87% for silver.

Sulfide Results: Results from the P80 10 mesh on sulfide material averaged recoveries of 70% recovery for gold and 53% recovery for silver while P80 150 mesh on sulfide material averaged recoveries of 85% for gold and 66% for silver, and P80 200 mesh recoveries on sulfide material averaged recoveries of 83% for gold and 65% for silver. Tables 13.4 and 13.5 respectively.

Conclusion: The 10% difference in gold recovery between bottle roll material ground to 10 mesh and bottle roll material ground to 150 mesh indicates that recoveries are susceptible to particle size. Thus Au and Ag recoveries could be enhanced by decreasing particle size to 150 mesh. However, going from 150 mesh to 200 mesh did not measurably improve recoveries.

Table 13.1 Drill Holes Used to Make Metallurgical Composites

rill Holes Used to Make Composites

ROM heap leach gold and silver recoveries have been extrapolated from the previous data and are estimated to be 60% for gold recovery and 57% for silver recovery.

14 MINERAL RESOURCE ESTIMATION

14.1 INTRODUCTION

MMC was contracted by Rye Patch to complete a new resource estimate for the Lincoln Hill Project. Since the last report was authored, Rye Patch US drilled 55 RC holes and 5 diamond holes at Lincoln Hill. Geologic cross sections were created and updated and Rye Patch US wanted to make sure that the geologic interpretation would be used to guide the grade estimation process. Rye Patch US has validated the existence of mineralization with its own drilling programs.

The resources stated for Lincoln Hill in this report conform to the definitions adopted by the Canadian Institute of Mining, Metallurgy and Petroleum (CIM), December 23, 2005, and meet the criteria of Inferred Mineral Resources.

The Lincoln Hill Mineral Resource is not materially affected by any known environmental, permitting, and legal, title, taxation, socio-economic, political or other relevant issues.

14.2 DRILLING DATA

Lincoln Hill drill data was provided in Microsoft Access format. The dataset includes collar coordinates, downhole survey information (when collected), assays and geologic codes. The database comprises 124 exploration holes covering 16,922 meters of assays. MMC validated the database and has certified the data to be clean and error free. The drillhole database has been converted into a Vulcan Isis database.

14.3 TOPOGRAPHIC DATA

The topography for Lincoln Hill was derived from the USGS Quad699 digital elevation model. The DEM was transformed into an Autocad DXF file. The file was then imported in Surfer and topography strings were generated. The topography was used to ensure that no mineralization was estimated into the air at Lincoln Hill.

14.4 COMPOSITES

All samples were composited to a constant three meter sample length.

Drillhole assays were composited using three meter down-the-hole compositing. The top of the hole is where compositing began in order to calculate the top and bottom of composites. The interpreted geologic shapes were then used to flag the composite with geologic codes.

14.5 GEOLOGIC MODEL

Rye Patch re-evaluated the lithological units at Lincoln Hill after the 2010 and 2011 drilling programs. The results have defined lithologies that have been displaced by typical basin and range normal faulting. The information was given to MMC in AutoCAD format. The AutoCAD files were used as a reference when construction of the geologic model took place. MMC worked closely with a Rye Patch US geologist during the geologic model construction process. The interpretation resulted in 3D solids and surfaces that represent different geologic features of the Lincoln Hill deposit.

The rock types modeled at Lincoln Hill are shown in a typical cross section (Figure 14.1) were:

- Lamprophyre Dikes
- Sericite Felsic Volcanics
- Silicified Felsic Volcanic Tuff
- Andesite

Figure 14.1 shows a North East cross section through the geologic model at Lincoln Hill. The same section through the block model displaying Au grades is shown in Figure 14.2. Figure 14.3 shows and isometric view of the Lincoln Hill modeled Geology.

Figure 14.1 Typical Lincoln Hill NE Cross Section (Looking NW)

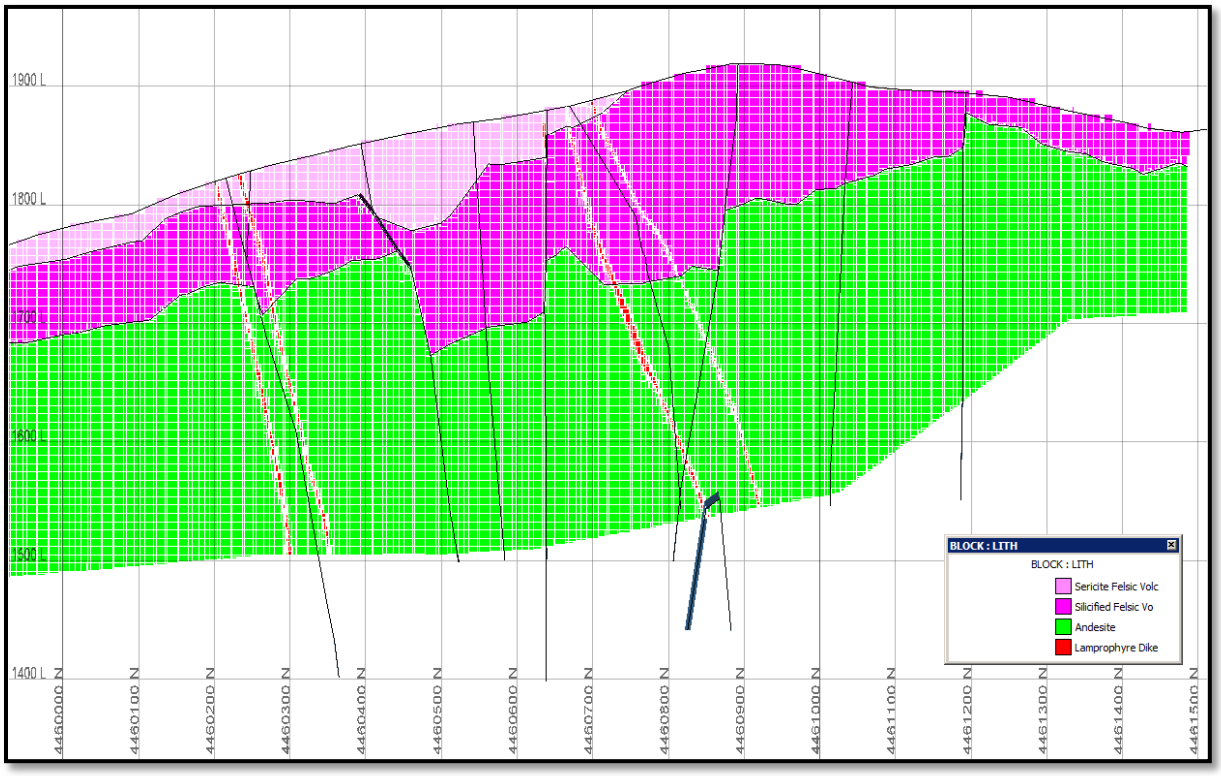

Figure 14.2 Typical Lincoln Hill NE Cross Section (Looking NW)

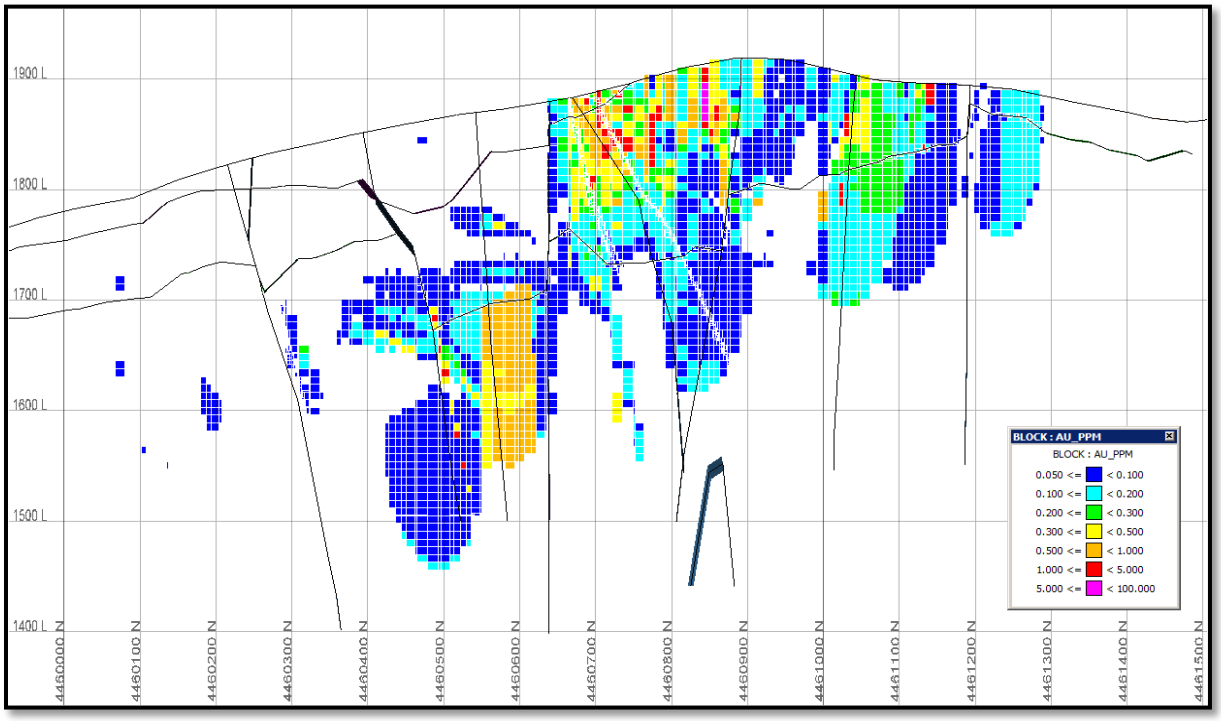

Figure 14.3 Isometric View of Lincoln Hill Modeled Geology

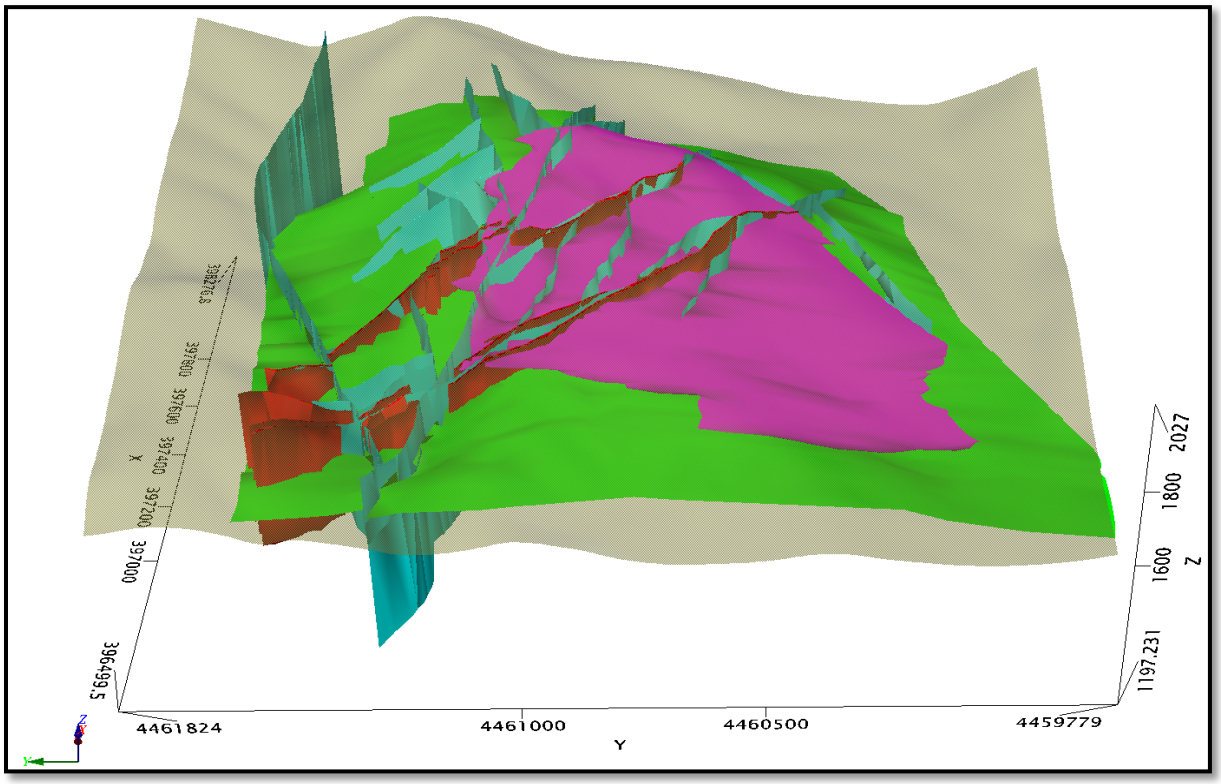

14.6 SPECIFIC GRAVITY

Densities were applied to the resource model according to the following table:

Table 14.1 Material Type Densities

Rock Type	Density (g/cm3)
Lamprophyre Dyke	2.52
Sericite Felsic Volcanics	2.52
Silicified Felsic Volcanics	2.52
Andesite	2.61

14.7 RESOURCE MODEL

Both gold and silver mineralization was estimated for the Lincoln Hill Deposit using 100 exploration drill holes. There were a total of 5,495 three-meter-length gold and silver composites used in the estimation. The results were calculated using Vulcan software and stored in a Vulcan block model. MMC used Inverse Distance to the third power for the estimate technique.

14.7.1 RESOURCE MODEL DIMENSIONS

Table 14.2 Lincoln Hill - Resource Model Dimensions (m)

	Item	North	East	Elev.
Parent Blocks	Minimum	396700	4460000	1400
	Maximum	398009	4461610	2065
	Number of Blocks	187	230	95
	Block Size	7	7	7
Sub Blocks	Minimum	396700	4460000	1400
	Maximum	398009	4461610	2065
	Number of Blocks	1309	1610	665
	Block Size	1	1	1

14.7.2 GRADE ESTIMATE

Resources were estimated spatially into the block model based on geological constraints and observations. A multiple pass estimation technique was employed in order to properly quantify the mineralization characteristics for Lincoln Hill. Resources were estimated globally to reflect the disseminated portion of the deposit. This was followed by an estimation of the vertical high grade structures of the deposit. The high grades were limited to narrow vertical ellipses and not used for estimation of the bulk of the ore deposit.

Gold and silver was estimated using Inverse Distance estimation techniques. A minimum of 1 composite was used in order for a block to be estimated. A maximum 25 samples were used. Sample selection was

limited to 4 samples per drillhole. Au was capped to 15 g/t for the disseminated mineralization and 50 g/t for the veins. Ag was not capped.

Table 14.3 First Pass Estimation Parameters

First Pass Estimation Parameters	
Major axis	Bearing 140 – 150 meter radius
Semi Major Axis	Bearing 0 – 50 meter radius
Minor axis	Bearing 0 – 150 meter radius
Inverse Distance Weighting	2
Minimum Samples	1
Maximum Samples	25
Max Samples per hole	4
Capping	15 g/t Au – Ag not capped

Table 14.4 Second Pass Estimation Parameters

SecondFirst Pass Estimation Parameters	
Major axis	Bearing 140 – 150 meter radius
Semi Major Axis	Bearing 0 – 10 meter radius
Minor axis	Bearing 0 – 150 meter radius
Inverse Distance Weighting	2
Minimum Samples	1
Maximum Samples	3
Max Samples per hole	2
Capping	50 g/t Au – Ag not capped

14.7.3 RESOURCE CLASSIFICATION

Resource classification was based on the distance to the nearest sample and the number of samples used in the block-by-block estimation result. MMC based its classification criteria on increasing geological confidence, drill hole density and its clear understanding of the geologic controls at Lincoln Hill. Canadian National Instrument NI43-101 and the CIM standards (2005) implicitly define classification of mineral resources and MMC has followed those guidelines.

Table 14.5 lists the classification methodology used at Lincoln Hill.

Table 14.5 Lincoln Hill Resource Classification Criteria

Resource Code	Resource Class	Minimum Number of Holes	Distance (Meters)
1	Measured	2	15
2	Indicated	2	60
3	Inferred	1	60

14.7.4 MINERAL RESOURCES

Canadian National Instrument NI43-101 and the CIM Standards (2005) define Mineral Resources such that:

> *Mineral Resources are sub-divided, in order of increasing geological confidence, into Inferred, Indicated and Measured categories. An Inferred Mineral Resource has a lower level of confidence than that applied to an Indicated Mineral Resource. An Indicated Mineral Resource has a higher level of confidence than an Inferred Mineral Resource but has a lower level of confidence than a Measured Mineral Resource.*
>
> *A Mineral Resource is a concentration or occurrence of diamonds, natural solid inorganic material, or natural solid fossilized organic material including base and precious metals, coal, and industrial minerals in or on the Earth's crust in such form and quantity and of such a grade or quality that it has reasonable prospects for economic extraction. The location, quantity, grade, geological characteristics and continuity of a Mineral Resource are known, estimated or interpreted from specific geological evidence and knowledge.*
>
> *The term Mineral Resource covers mineralization and natural material of intrinsic economic interest which has been identified and estimated through exploration and sampling and within which Mineral Reserves may subsequently be defined by the consideration and application of technical, economic, legal, environmental, socio-economic and governmental factors. The phrase "reasonable prospects for economic extraction" implies a judgment by the Qualified Person in respect of the technical and economic factors likely to influence the prospect of economic extraction. A Mineral Resource is an inventory of mineralization that under realistically assumed and justifiable technical and economic conditions might become economically extractable. These assumptions must be presented explicitly in both public and technical reports.*

The oxide and sulphide mineralization for the Lincoln Hill project at various gold equivalent cutoff grades are listed in Table 14.6 and Table 14.7. Silver is reported at the gold cutoff grade as a contained metal secondary product.

0.9	570	1.56	29	45.23	829
1	523	1.62	27	39.87	670

14.7.5 INFERRED MINERAL RESOURCES

Canadian National Instrument NI43-101 and the CIM Standards (2005) define Inferred Mineral Resources as:

> *that part of a Mineral Resource for which quantity and grade or quality can be estimated on the basis of geological evidence and limited sampling and reasonably assumed, but not verified, geological and grade continuity. The estimate is based on limited information and sampling gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes.*
>
> *Due to the uncertainty that may be attached to Inferred Mineral Resources, it cannot be assumed that all or any part of an Inferred Mineral Resource will be upgraded to an Indicated or Measured Mineral Resource as a result of continued exploration. Confidence in the estimate is insufficient to allow the meaningful application of technical and economic parameters or to enable an evaluation of economic viability worthy of public disclosure. Inferred Mineral Resources must be excluded from estimates forming the basis of feasibility or other economic studies.*

The ***oxide*** inferred mineral resources at various cutoff grades for the Lincoln Hill deposit are listed in Table 14.8.

Table 14.8 Lincoln Hill Inferred Oxide Resource

1	388	1.49	19	42.39	529

14.7.6 INDICATED MINERAL RESOURCES

Canadian National Instrument NI43-101 and the CIM Standards (2005) define Indicated Mineral Resources as:

> *that part of a Mineral Resource for which quantity, grade or quality, densities, shape and physical characteristics can be estimated with a level of confidence sufficient to allow the appropriate application of technical and economic parameters, to support mine planning and evaluation of the economic viability of the deposit. The estimate is based on detailed and reliable exploration and testing information gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes that are spaced closely enough for geological and grade continuity to be reasonably assumed.*
>
> *Mineralization may be classified as an Indicated Mineral Resource by the Qualified Person when the nature, quality, quantity and distribution of data are such as to allow confident interpretation of the geological framework and to reasonably assume the continuity of mineralization. The Qualified Person must recognize the importance of the Indicated Mineral Resource category to the advancement of the feasibility of the project. An Indicated Mineral Resource estimate is of sufficient quality to support a Preliminary Feasibility Study which can serve as the basis for major development decisions.*

The ***oxide*** indicated mineral resources at various cutoff grades for the Lincoln Hill deposit are listed in Table 14.10.

Table 14.10 Lincoln Hill Indicated Oxide Resource

0.9	123	1.88	7	37.06	147
1	110	1.99	7	32.79	116

14.7.7 MEASURED MINERAL RESOURCES

Canadian National Instrument NI43-101 and the CIM Standards (2005) define Measured Mineral Resources as:

> *that part of a Mineral Resource for which quantity, grade or quality, densities, shape, and physical characteristics are so well established that they can be estimated with confidence sufficient to allow the appropriate application of technical and economic parameters, to support production planning and evaluation of the economic viability of the deposit. The estimate is based on detailed and reliable exploration, sampling and testing information gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes that are spaced closely enough to confirm both geological and grade continuity.*
>
> *Mineralization or other natural material of economic interest may be classified as a Measured Mineral Resource by the Qualified Person when the nature, quality, quantity and distribution of data are such that the tonnage and grade of the mineralization can be estimated to within close limits and that variation from the estimate would not significantly affect potential economic viability. This category requires a high level of confidence in, and understanding of, the geology and controls of the mineral deposit.*

The ***oxide*** measured mineral resources at various cutoff grades for the Lincoln Hill deposit are listed in Table 14.12.

Table 14.12 Lincoln Hill Measured Oxide Resource

Measured Oxide Resource					
Cutoff (Au g/t)	Tonnes (x1,000)	Au g/t	Au Ounces (x1,000)	Ag g/t	Ag Ounces (x1,000)

14.7.8 MINERAL RESOURCES

The Lincoln Hill mineral resources are tabulated by open pit mining cutoff grade assumptions. Mineral Resources are confined to the Project mineral tenure. The Mineral Resource was tabulated at a gold equivalent cutoff grade of 0.10 gpt for oxide and 0.20 gpt for sulphide mineralization. The mineral resource estimate was prepared in compliance with Canadian National Instrument 43-101 and followed the guidance of the Canadian Institute of Mining - Definition Standards for Mineral Resources and Mineral Reserves (2005). Table 14.14 and

15 MINERAL RESERVE ESTIMATES

Not applicable to this report.

16 MINING METHODS

This section of the report describes the mining assumptions used in the PEA. The mining operation was assumed to employ conventional surface mining methods, with drill and blast rock breakage and truck and loader materials handling. The global resource model described in Section 14 was used to develop a surface mine shell using Lerch-Grossman optimization in the Gemcom Whittle software package. A production schedule was then developed using the MineMax Scheduler software package to schedule mineralized material to process facilities for treatment and overburden material to storage facilities. The production schedule was constrained to produce a constant feed of mineralized material to a heap leach pad. Some stockpiling of mineralized material was required to balance the plant feed rate over the life of mine (LOM).

16.1 PIT SLOPES

No site specific geotechnical studies have been undertaken to date, and therefore pit slopes were based on reasonable assumptions and observation of nearby operating surface mines. An overall pit slope of 45° was used for pit optimization. This is typically a more than attainable pit slope for open pit mines in Nevada, barring any unusual geotechnical issues.

The Rochester Mine, owned and operated by Coeur D'Alene Mines, is currently open pit mining approximately five kilometers away from proposed pits at Lincoln Hill. According to their December, 2012 technical report highwall slopes ranging from 48° to 57° are used there. Given slopes up to 57° the current 45° assumption for Lincoln Hill may be conservative, but further geotechnical studies are required.

16.2 WHITTLE LEARCH GROSSMAN DETERMINATIONS

Whittle requires various inputs in order to create the design pit shells input to Vulcan for a manual design. These include:

- The resource model, including mined out topography.
- Pit slope angles.
- Mining cost as per tonne mined.
- Processing and general and administrative (G&A) expenses as a cost per tonne of material processes.
- Process recovery for gold and silver.
- Sale prices for gold and silver.

The following inputs were used in the pit optimization:

- Overall pit slopes of 45° were used for all high wall orientations.
- Mining cost of $2.50 per tonne was used assuming contractor mining. This cost was applied equally to all rock types in the model.

- Processing costs were initially estimated at $3.36 for processing and $1.00 G&A for a total of $4.36. Later revisions set the processing cost at $3.60 with $1.50 G&A for a total cost of $5.10.
- Process recovery was initially estimated at 60% for gold and 57% for silver.
- Pits were optimized for a large range of gold and silver prices. Optimizations started at $300/t.oz. Gold and $5.25/t.oz. Silver and were run in $25 gold increments to $1500/t.oz. Gold and $26.25/t.oz. Silver.
- The final pit used for scheduling and representing the "minable resource" used a gold price of $775/t.oz. Gold and $13.56/t.oz. Silver.

Multiple economic scenarios were analyzed varying process capacity and mining rate in order to determine what pit to use.

16.3 MINABLE RESOURCES

Classification	Mineralized Material Tonnes x 1,000	Gold Grade g/t	Gold Ounces x 1,000	Silver Grade g/t	Silver Ounces x 1,000
Measured	1,567	0.62	31	12.9	648

16.5 MINING EQUIPMENT

This PEA assumes that mining operations at Lincoln Hill will be fully contracted. The short mine life and developing nature of the company make contract mining the economic and low risk choice.

The contract fleet will need to move a maximum of 8,000 tonnes per day. This will likely be done with trucks in the 30 to 90 tone range and appropriately sized wheel loaders or excavators for loading. Ancillary equipment will include a water truck, dozer(s), grader(s) and blast hole drills.

With a run of mine heap leaching as the only process, there will be no need for stockpiling and re handling.

17 RECOVERY METHODS

Test work performed on the Lincoln Hill material indicates this material is great candidate for cyanide leaching as a gold and silver recovery method. Both heap leaching and milling/CIL process schemes would be acceptable cyanide leaching methods for this material. Preliminary economic models indicated that heap leaching provided the best return for the project in today's precious metals market. Thus the recovery method chosen for this assessment is heap leaching.

The currently envisioned recovery method includes processing ROM material at a production rate of 4,400 tpd which would be delivered to the heap leach pad for cyanide leaching. A primary leach cycle of 120 days, total leach cycle of 200 days, and total heap leach material of 8 million tonnes has been used to estimate the pad storage capacity and production lift heights. Cyanide leach solution application rates have been initially estimated at 0.16 l/min/m^2 (0.004 gpm/ft^2). ROM heap leach gold and silver recoveries are predicted to be 60% for gold and 57% for silver.

Pregnant leach solution flow from the leach pad will average about 567 m^3/hr (2500 gpm) which will report to a Merrill Crowe precious metals recovery plant. The Merrill Crowe plant will produce a gold / silver precipitate that will be processed to doré in an onsite refinery. The doré will be sent to an offsite processing facility for final gold / silver separation and refining.

18 PROJECT INFRASTRUCTURE

The Lincoln Hill project is ideally located with nearby access to roads, power, pro-mining communities and relatively flat land for building heap a heap leach pad.

18.1 ACCESS

Lincoln hill is located approximately 12km by road from exit 119 on Interstate 80 west of Lovelock, NV. Of that 12km, 4km are paved and the remaining 8km are dirt road in good repair. An alternate route exists heading south from Lincoln Hill across The Packard Flat on approximately 14km of dirt roads to Coal Canyon Road which meets Interstate 80 at exit 112.

18.2 POWER

High voltage power lines run approximately 10km from the Lincoln Hill project. These lines also power the Coeur Rochester mine to the west of Lincoln Hill and Relief Canyon to the south. The potential may exist to tap into supply lines for the Rochester mine that run closer to the Lincoln Hill project, but at the most 10km of new service lines will have to be built.(figure 18.1)

18.3 PERSONNEL

Lincoln Hill is located in an area with multiple operating open pit mines giving ample access to skilled personnel. From the project site the four most notable population centers are:

- Lovelock, NV. A 23km drive west of exit 119 on Interstate 80. Lovelock has a population of 2,000 people.
- Winnemucca, NV. A 94km drive east of exit 119 on Interstate 80. Lovelock has a population of 7,200 people.
- Fernley, NV. A 118km drive west of exit 119 on Interstate 80. Lovelock has a population of 19,400 people.
- Reno, NV. A 172km drive west of exit 119 on Interstate 80. Reno is the largest city in Northern Nevada with a population of 225,000 people.

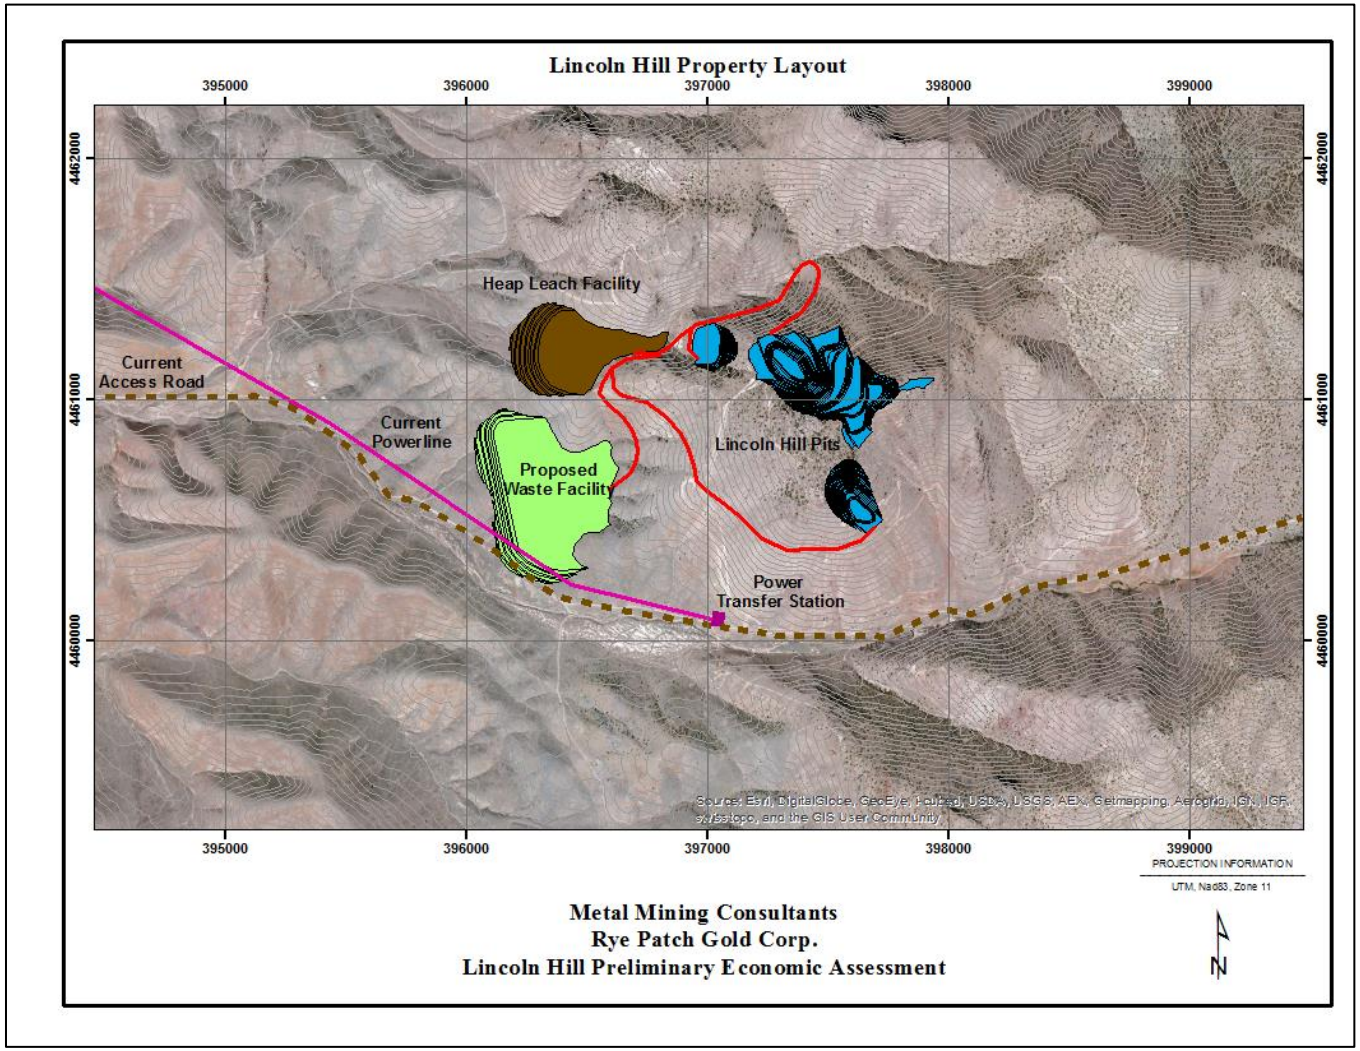
18.4 HEAP LEACH PAD

A 1 million square foot leach pad capable of holding 8 million tonnes of mineralized material will be built south of the mine pit on the Packard Flat. This is the closest relatively flat land amenable to leach pad construction. (Figure 18.1)

18.5 OVERBURDEN STORAGE

Overburden storage will be directly adjacent to the pit on the south west side. The facility will be built out from the hill side with maximum slope angles of 2.5:1 for simplified reclamation. (Figure 18.1)

Figure 18.1 Lincoln Hill Property Layout



19 MARKET STUDIES AND CONTRACTS

The study assumes that a gold-silver dore will be produced on site at Lincoln Hill, and sold on to a gold refiner offsite. No transport and refining charges have been considered in the analysis and no contracts for delivery of gold dore have been established due to the preliminary nature of the evaluation.

It has been assumed that gold would be sold on the spot market, which has historically been able to absorb the entire world production.

No contracts for materials delivery, electrical supply or maintenance have been established.

20 ENVIRONMENTAL STUDIES, PERMITTING AND SOCIAL OR COMMUNITY IMPACT

20.1 INTRODUCTION

Currently Rye Patch is authorized to conduct mineral exploration within the Project under multiple Notices with the United States Bureau of Land Management (BLM) and a State of Nevada Reclamation Permit. In addition, Rye Patch has initiated the process with the BLM to obtain an Exploration Plan of Operations and amend the State of Nevada Reclamation Permit for the Wilco Project.

In order to develop, operate, and close the Wilco Mine, Rye Patch will be required to obtain a number of environmental and other permits from the BLM, the State of Nevada, and Pershing County. In accordance Rye Patch Environmental, Health, and Safety, Rye Patch will comply with applicable federal and state environmental statutes, standards, regulations, and guidelines in the permitting of the Wilco Mine. Environmental baseline studies will need to be conducted at the mine and facility locations to meet federal and state requirements.

The issuance of a permit to mine on public lands administered by the BLM will be a federal action that has an impact on the quality of the human environment in the project area. Thus, the permitting process will require the preparation of an environmental impact statement (EIS) under the National Environmental Policy Act (NEPA), Council of Environmental Quality (CEQ) regulations, and BLM guidelines and procedures.

The following sections provide more detailed information on the BLM Plan of Operation, the NEPA Process, the State of Nevada permit requirements, and the needed environmental baseline studies requirements

20.1.1 BLM PRE-APPLICATION PLANNING

As part of the pre-application planning process with the BLM, Rye Patch will meet with the BLM to discuss the anticipated scope of the mining operation and review the likely environmental baseline data needs for the process of the Mine Plan of Operations This initial meeting generally occurs between one and two years prior to the submittal of the Mine Plan of Operations, depending on the anticipated complexity of the mining operations and environmental baseline data needs. The process for collecting the needs baseline data generally includes the development of a baseline data collection work plan, which is submitted to the BLM for review approval prior to initiating the baseline data collection. Next is the collection of the baseline data and development of a report that documents and summarized the data collected. This report is then submitted to the BLM for review and approval. In some cases the baseline data collection process will also involve the State of Nevada, depending on the environmental resource. For the Wilco Mine the currently anticipated environmental baseline data needs include, but are not limited to the following: Ore and waste rock geochemical characterization; ground water characterization and modeling, including pit lake modeling; geochemical modeling; air quality modeling; botanical and wildlife surveys, include noxious weeds; socioeconomic assessment; visual assessment; and cultural resources inventory.

20.1.2 PLAN OF OPERATIONS PROCESSING

A Mine Plan of Operations is prepared using the format accepted by the BLM and the NDEP, Bureau of Mining Regulation and Reclamation (BMRR). The Mine Plan of Operations describes the operational procedures for the construction, operation, and closure of the Wilco Mine. As required by the BLM, the Mine Plan of Operations includes a waste rock management plan, quality assurance plan, a storm water spill contingency plan, reclamation plan, a monitoring plan, and an interim management plan. In addition, the Plan includes a Reclamation Cost Estimate (RCE) for the closure and reclamation of the Wilco Mine. The content of the Mine Plan of Operations is primarily based on the Rye Patch mine plan and mill design and the data gathered during the Pre-Application Planning Process. Once submitted to the BLM, the Mine Plan of Operations is assessed for technical completeness. Once determined to be technically complete, the processing of the Mine Plan of Operations enters an idle phase while the BLM completes their NEPA Process. Near the end of the NEPA Process the BLM recommences review of the Mine Plan of Operations to complete the final assessment of the document and determine if the RCE is adequate for the bond on the project. This final review is coordinated with the BMRR, since the two agencies must concur of the bond amount for the project.

20.2 NEPA/EIS RECORD OF DECISION

The approval of the Plan of Operation for technical completeness by the BLM will trigger a NEPA review process that will require the preparation of an EIS with the BLM as the lead agency. Rye Patch will likely enter into a Memorandum of Understanding (MOU) with the BLM for a third-party EIS Contractor to complete the EIS preparation with the BLM. The MOU will define the roles of the BLM and Rye Patch in the preparation of the EIS, require a professional services agreement between Rye Patch and the third-party EIS Contractor, a disclosure statement of no conflict of interest from the third-party EIS Contractor, and a schedule for the completion of the EIS. The culmination of the EIS process, following other federal agency and public review and comment, will result in a Record of Decision and subsequent approval of the Plan of Operations by the BLM.

20.3 STATE OF NEVADA PERMITS

The State of Nevada requirements a number of major environmental permits in order for the Wilco Project to be developed. From the Nevada Division of Environmental Protection (NDEP) issues permits that address water and air pollution, as well as land reclamation. The Nevada Division of Water Resources (NDWR) issues water rights for the use of water at a project. The Nevada Department of Wildlife (NDOW) issues a permit to protect wildlife of toxic solutions.

20.3.1 NDEP RECLAMATION PERMIT

The Nevada Reclamation Permit (NRP) application is the same document used for the BLM Mine Plan of Operations. This application and permit addresses all surface disturbing activities regardless of surface ownership.

20.3.2 NDEP WATER POLLUTION CONTROL PERMIT

The WPCP application will be for the open pit mine, waste rock dump, mining activities, and the processing facilities. The WPCP application will include an engineering design for the waste rock dump, a waste rock characterization report, a heap leach characterization report, and a modeling report for the closure of the waste rock dump and the heap leach facility, as well as an engineering design for the Project process components.

The Engineering Design Report will provide a detailed review of all available data, including topographic data which we have assumed requires updating for this proposal. Once the data is reviewed and a gap analysis provided, alternate sites will be conceptually reviewed for merits and one or more sites will be selected as potential tailings and dump locations. A detailed sampling program will be provided and contracts let to gather the required missing data.

1) Heap leach design will include the following elements:
2) Pad design and loading plan;
3) Water balance;
4) Storm water analysis and diversion design;
5) Siting evaluation (assume no tradeoff analysis at this point);
6) Construction materials inventory;
7) Mass balance (storage);
8) Deposition plan;
9) Water management plan; and
10) A detailed review and design for closure.

The waste rock dump design will include stability and storm water considerations as well as containment and closure options to protect waters of the state.

20.3.3 NDEP AIR QUALITY OPERATING PERMIT

The Project will require an Air Quality Operating Permit (AQOP) application using Bureau of Air Pollution Control (BAPC) forms. The Application will include a description of the Facility and include a detailed emission inventory. The Application will also include locations, plot plans, and process flow diagrams. Once the Application is submitted to BAPC, communications with the BAPC will be necessary to ensure that the Application is processed in a timely manner. Once BAPC issues a draft permit, a review of it will be necessary to ensure that the content of the permit is consistent with the Application submitted to BAPC, as well as the regulatory requirements.

20.3.4 NDWR WATER RIGHTS

Rye Patch will require water rights from the Nevada Division of Water Resources (NDWR) to remove and utilize the water for the mining and processing operation and to provide water for the public water system. Once an application is filed with the NDWR it will be reviewed for completeness. There is a public review and protest process and it is likely that the permit will be protested. This is because the project is located in the Humboldt River drainage and the Humboldt River Basin Water Authority

generally protests all new and revised water rights. As a result the timeframe for obtaining the water rights will be nine to 12 months.

20.3.5 NDOW INDUSTRIAL ARTIFICIAL POND PERMIT

The development of the process ponds at the processing facility, which is part of the water management system, will require an industrial artificial pond permit (IAPP) from the Nevada Department of Wildlife (NDOW). A complete the application for the IAPP will need to be prepared and submit to the NDOW. It will be important to maintain communication with the NDOW to ensure that the permit is issued in a timely manner.

20.4 PERSHING COUNTY

Pershing County requires the issuance of a special use permit (SUP) for mining operations. The SUP application requires the type and extent of operations, particularly the amount transportation activities. The county uses the SUP process to ensure that a road maintenance agreement is executed to have the mining operator assist in the maintenance of those county roads used by the project.

20.5 OTHER MINISTERIAL PERMITS

In addition to the major environmental permits outlined above, the following table lists potential other notifications or ministerial permits that would likely be necessary to operate the Project.

Table 20.1 Ministerial Permits, Plans and Notifications

Notification/Permit	Agency	Timeframe	Comments
Mine Registry	Nevada Division of Minerals	30 days after mine operations begin	
Mine Opening Notification	State Inspector of Mines	Before mine operations begin	
Solid Waste Landfill	Nevada Bureau of Waste Management	180 days prior to landfill operations	
Hazardous Waste Management Permit	Nevada Bureau of Waste Management	Prior to the management or recycling of hazardous waste	
General Storm Water Permit	Nevada Bureau of Water Pollution Control	Prior to construction activities	
Hazardous Materials Permit	State Fire Marshall	30 days after the start of operations	
Public Water Supply	Nevada Bureau of Safe Drinking Water	Prior to construction activities	
Septic System	Nevada Bureau of Water Pollution Control	Prior to construction activities	
Fire and Life Safety	State Fire Marshall	Prior to construction	

Notification/Permit	Agency	Timeframe	Comments
Explosives Permit	Bureau of Alcohol, Tobacco, and Firearms	Prior to purchasing explosives	Mining contractor may be responsible for permit
Notification of Commencement of Operation	Mine Safety and Health Administration	Prior to start-up	
Radio License	Federal Communications Commission	Prior to radio use	

21 CAPITAL AND OPERATING COSTS

Capital and operating costs have been developed using information available from the CostMine cost data service by InfoMine USA, Inc. This basic data was reviewed in discussions with staff at operating mines in Northern Nevada where heap leach processing was underway to assure that the estimates represented the range of practice.

A conceptual basis for the development of site infrastructure (heap leach pad, overburden storage facility, roads, shops offices, process plant) was defined as the basis for capital cost estimates. The capital costs were developed based on a nominal mining rate of 8,000 tonnes per day, processing 1.56 million tonnes per annum. The estimate includes facilities, mobile equipment and sustaining capital required over the LOM.

Cost accuracy is estimated to be + or – 35%. All costs are in constant USD from Q1 2014, without escalation for inflation – summarized in Table 21.1.

Table 21.1 Project Capital and Cost Summary

Cost	Initial	Sustaining
Carbon Stripping and Regeneration	$2,697,000	
Refining	$717,000	
Reagents	$2,122,000	
Plant Mobile Equipment	$2,464,000	
Leach Pad and MC Plant (4.378 million ft2)	$3,150,000	
Site Roads	$2,206,000	
Administrative Building / Lab	$717,000	
Initial Capital	$14,073,000	
Working Capital		$4,066,197
Owners Cost	$2,000,000	
Initial Indirect Cost (includes contingency)	$9,147,450	
Royalty Purchase	$1,000,000	
Total	**$26,220,450**	**$4,066,197**

21.1 CAPITAL COSTS

The Construction capital cost is listed in Table 21.1 and consists of costs associated with project construction which is assumed to begin in year -1, prior to production. Sunk costs associated with Feasibility Studies, Permitting and finance are not included in the evaluation. The construction capital costs include direct costs, indirect costs, Owner's costs and contingency. Direct capital cost includes the initial heap leach pad construction, Merrill Crowe plant and refinery, infrastructure buildings and services, site roads, and any mobile equipment. Indirect costs included Engineering, Procurement and Construction Management (EPCM). Owner's cost includes an allowance for property maintenance and development of management team and workforce, and the training of the workforce. Capital costs were developed based on scaling costs from similar facilities for production rates and from design basis

assumptions including a contractor operated mining fleet. The estimated life of mine capital costs for the base case is summarized in Table 21.2:

Table 21.2 Life of Mine Estimated Capital Costs

Description	US$ (millions)
Initial Capital	14.2
Working Capital	4.0
Indirect, Sustaining, Owner and Royalties	12.0
Total	**30.2**

21.2 OPERATING COSTS

Operating cost assumptions were based on similar scale surface mining operations using heap leach processing in northern Nevada, and process cost estimates for key consumables based on the available metallurgical test data, power consumption data and prevailing costs for key materials in similar Nevada mining operations. Reclamation cost is consistent with the projected scale of the mining operation. More definitive estimates will require detail design of the facilities Operating cost assumptions per tonne of material processed are summarized as follows:

Table 21.3 Unit Operating Costs

Cost Category	US$ (Per Tonne Processed)
Waste Mining Cost	$2.50
Ore Mining Cost	$3.10
Heap Leach Processing	$3.60
General and Administrative	$1.50
Reclamation	$0.76
Total	**$11.46**

22 ECONOMIC ANALYSIS

It is a common practice in the authorship of NI-43-101 scoping studies to look at a project on a ten years operating basis. Assuming mine production of ten years to complete a project allows the engineer to determine the size of mining equipment and processing equipment and then determine the Capital on Operating requirements for the project. The section 16 production schedule of 5 years presents our recommendation as strong argument to that this project could be advanced profitably.

We based this economic evaluation on the schedule of production physicals from Section 16 and the capital and operating cost estimates in Section 21. The evaluation assumes constant US dollars from Q1 2014 and it considers taxes and royalties. A constant gold price of $US 1,350 per Au ounce and a constant silver price of $US 22 per Ag ounce were assumed for a base case evaluation.

This PEA is preliminary in nature, and is based on technical and economic assumptions which will be evaluated in more advanced studies. The PEA is based on the Project in-situ resource model (SEWC 2012) which consists of material in Measured, Indicated and Inferred classifications. Inferred mineral resources are considered too speculative geologically to have technical and economic considerations applied to them. The current basis of project information is not sufficient to convert the in-situ mineral resources to Mineral Reserves, and mineral resources that are not mineral reserves do not have demonstrated economic viability. Accordingly, there can be no certainty that the results estimated in this PEA will be realized. The PEA results are only intended as an initial, first-pass review of the potential project economics based on preliminary information.

22.1 ECONOMIC PERFORMANCE

Mining physicals in the production schedule was used with unit operating cost assumptions from Section 21 to calculate annual operating costs. Capital costs were input on an annual basis using a conceptual schedule for construction in year -1, followed by working capital over the 5 year mine life. Economic and physical performance parameters are listed in Table 22.1, for the base case price assumptions, and for spot price assumptions as at May 21, 2014.

At a gold price of US$1350 per ounce and a silver price of $22 per ounce, the base case has a US$78.4 million pre-tax net cash flow, a US$64.2 million net present value at a 5% discount rate, and an internal rate of return of 76.5%. as in Table 22.1. At US$1450 gold and US$25 silver, the total pre-tax net cash flow increases by 22% over the base case to US$95.1 million, the net present value increases to US$78.6 million and the internal rate of return improves to a robust 90.7%.

Table 22.1 Base Case Assumptions

Base Case Assumptions		
Metal Prices		
Gold	USD$	$1,350
Silver	USD$	$22
Average Annual Production (Contained from Mine)		
Gold	ounces	33,000
Silver	ounces	753,000
Peak Annual Production (Contained from Mine)		
Gold	ounces	63,700
Silver	ounces	1,011,000
Pre-Production Capital Costs	USD$	$26.2 M
LOM Sustaining Capital Costs	USD$	$4.0 M
Pre-Production Period	Years	1
Mine Life	Years	5
Pad Life	Years	7
Cash Cost Per Gold Equivalent Ounce	USD$	$575
Pre Tax		
Life of Mine NPV at 5% Discount Rate	USD$	$64.2 M
Internal Rate of Return	%	76.5%
Payback Period	Years	1.3
After-Tax		
Life of Mine NPV at 5% Discount Rate	USD$	$40.9 M
Internal Rate of Return	%	53.0%
Payback Period	Years	1.6

22.2 SENSITIVITY ANALYSIS

Graphical presentations of the sensitivity are shown as spider diagrams in Figure 22.1 which shows the change in IRR for proportional changes of operating cost, capital cost and gold recovery assumptions around the base case (100%), and in Figure 22.2, which shows the change in NPV@5% for proportional changes in operating cost, capital cost and gold recovery assumptions around the base case (100%).The sensitivity analysis indicates that the project economic performance is most sensitive to gold price or metal recovery over the range of 75% to 125% in gold price/recovery.

MMC chose to evaluate sensitivities based on three changing parameters: metal prices, capital costs and operating costs. Though the sensitivity analysis of gold and silver was run, silver is a small component and has very little impact on the value of the project. Figure 22.1 shows the project is more sensitive to changes in gold price.

The sensitivity of projected economic performance has been evaluated over a range of gold price assumptions between $US 1,012.50 - $US 1,687.50 per ounce (silver price constant - $22.00 per ounce) and the results are listed in Table 22.3. The projected economic performance was also evaluated for silver between a range of $US 16.50 - $US 27.50 per ounce (gold price constant - $1,350 per ounce) and

the results are listed in Table 22.4. Sensitivity to operating cost and capital cost were investigated over a range of 75% - 125% of the base case assumptions, and are listed in Tables 22.5 and 22.6, respectively.

Figure 22.1 Sensitivity of Project IRR to Changes in Operating and Capital Costs

23 ADJACENT PROPERTIES

There are active mining operations, advanced stage exploration properties and early stage exploration properties within 8 km (5 mi) of Lincoln Hill. The Coeur Rochester silver mine is approximately 3.2 km (2 mi) to the east and the Spring Valley property of Midway/Barrick is approximately 4.8 km (3 mi) to the northeast. Additionally, Rye Patch has the advanced stage exploration property, Wilco, located approximately 8 km (5 mi) southwest of Lincoln Hill. All of these properties have been explored in the past but recent work has defined new or additional resources.

The Spring Valley property and Lincoln Hill have some geological characteristics in common based on the recent report on Spring Valley (LeLacheur and others, 2009). They are both hosted in the Permo-Triassic Rochester Rhyolite ash flow tuffs and flows although Spring Valley is lower in the stratigraphic section than Lincoln Hill. Both properties exhibit some similar mineralization and hydrothermal alteration features. Gold mineralization occurs in quartz veins and stockwork in quartz + sericite altered volcanic rocks with a halo of argillic alteration. Hydrothermal clay is reported in Spring Valley and hematite clay occurs in stockwork with gold mineralization at Lincoln Hill. Both properties are structurally complex with intersecting northwest and northeast trending fault and breccias are common in both. This discussion of the Spring Valley deposit is relevant because of the geological and mineralogical similarities between the two properties.

Due south of the project can be found the Relief Canyon Mine. The current owners, Pershing Gold Corporation, published a NI43-101 Technical Report on April 12, 2012. www.pershinggold.com. Pershing Gold is currently advancing their property to production.

The author has not verified the information contained in these technical reports and therefore the information in the reports is not necessarily indicative of the mineralization on the Lincoln Hill property.

24 OTHER RELEVANT DATA AND INFORMATION

There is no other relevant information regarding the Lincoln Hill property.

25 INTERPRETATION AND CONCLUSIONS

Rye Patch has invested considerable effort, in the advancement of the Lincoln Hill Property through drilling, permitting, technical and metallurgical evaluations, internally and with the assistance of reputable consulting firms. This evaluation indicates a strong positive performance of a heap leaching facility at Lincoln Hill at the current metal price environment. The project performance is most sensitive to gold price and gold recovery. Metallurgical data to this point indicates economic extraction of metals is not complicated.

Exploration potential adjacent to the project and within other Rye Patch controlled claims is positive with some untested targets.

The project economics suggest that this is a project that can be put into production for a capital investment of approximately US $26.3 million and being paid back within 2 years of startup. Lincoln hill is a project that warrants a more advanced review than a scoping study. Measured and Indicated Mineralization has been sufficiently identified and should be used as the basis of a Preliminary Feasibility Study.

26 RECOMMENDATIONS

26.1.1 PROJECT DEVELOPMENT

MMC recommends that Rye Patch should engage the services of a reputable consulting firm in the advancement of the project to the preliminary feasibility level. Lincoln Hill represents a resource which includes Measured and Indicated resources. MMC recommends the following plans should be investigated to develop a better knowledge of the deposit economic criteria.

26.1.1.1 OPEN PIT GEOTECHNICAL PROGRAM

The open pit design parameters presented in Section 16 have been developed with only limited geotechnical data on the rock mass and observations of neighboring mining operations. The methods used to estimate these parameters are reasonable for this preliminary economic assessment. It is recommended that the following activities be conducted to advance the design to the feasibility design level:

- Drill geotechnical core-holes to characterize the rock mass and collect samples for laboratory testing;
- Perform slope stability analysis of pit designs including:
    - Kinematic stability of benches,
    - Numerical analysis of global pit slopes that includes pit interaction with underground, and
    - Rock fall assessment of berms and set-back distances.

26.1.1.2 METALLURGY AND PROCESS DESIGN

Metallurgical studies have only been performed at a scoping level. The next phase of metallurgical investigation should include further metallurgical testing and detailed studies to more thoroughly evaluate the optimum process flow sheet and required process parameters.

26.1.1.3 INFRASTRUCTURE

For a feasibility study, MMC recommends Rye Patch begin:

- Transportation study for road enhancements and logistics from Lovelock to Lincoln Hill;
- Water study and site water balance; and
- Power line study and communication with local power suppliers.

26.2 RECOMMENDATION COSTS

MMC believes the proposed advancement programs will cost approximately $1.7 million as follows:

Table 26.1 Recommended Advancement Costs

Budget Item	Description	Cost, (1000's)
Geotechnical Studies and Drilling	Conduct infill drilling	US$600
Geology	Resource Model Updates	US$75
Geotechnical, Groundwater	Field and engineering work for preliminary	US$450

Budget Item	Description	Cost, (1000's)
Hydrology and Leach Pad	feasibility study	
Mining, Metallurgy and Economics	OP Mine Planning, Cost Estimation and Reserves	US$75
Metallurgical test work	Continue to feasibility level	US$200
Other	Environmental, Social, Archeological, Permitting	US$300
Total		**US$1,700**
